1. **LINEAR PROGRAMMING IN GROWTH MODELS OVER AN INFINITE HORIZON**

1.1 **Introduction.**

Practically all applications of the linear programming theory to growth models in the economy (2,265), (9,234), have in common that they limit themselves to a program over a finite horizon. Into many models, however, the fixation of a horizon introduces a certain arbitrariness (4,105) which can be avoided by formulating the problem over an infinite horizon. Then, mathematically speaking, a linear programming problem arises in an infinite dimensional space. This study presents a mathematical analysis of such a problem, which results in a general solving procedure. In this analysis we assume a particular characteristic with regard to the structure of the linear programming problem.

In this chapter four growth models will be discussed in macro economical terms, in order to arrive at a first formulation of the problem in an economical context, and to show that practically every realistic linear growth problem can be formulated into a model possessing the specific structure presumed in the mathematical treatment. As such, the models discussed are of secondary importance. The chapter will be concluded with a brief reference to the most important results.

Since chapter 2 presents a formal mathematical definition of the problem, and since its mathematical elaboration is not connected with the growth models outlined above, those exclusively interested in the mathematical treatment can skip this chapter without objection.

1.2 **Growth model I.**

We consider an economy with \( m \) goods and \( n \) production processes. The production processes are specified as follows:

a) The production processes are executed in a sequence of periods of equal duration. The input received at the beginning of a period results in an output available at the end.
b) The production processes are linear: for every period, the input and output of each production process is proportional to the level of activity at which it is executed during the period.

c) For each production process, the proportion between the quantity of input and output and the level of activity is constant for all periods.

We shall represent the activity levels at which the production processes are executed during the periods \( t = 0, 1, \ldots \) by a sequence of non-negative \( n \)-dimensional vectors \( x(0), x(1), \ldots \), in which \( x_j(t) \) is the activity level for the \( j \)-th production process, during the \( t \)-th period. The suppositions b) and c) imply that, for each sequence of activity levels \( x(0), x(1), \ldots \), the corresponding quantities of input and output may be expressed as follows:

\[
\begin{align*}
Bx(t), & \quad t \geq 0 \\
Ax(t), & \quad t \geq 0
\end{align*}
\]

(1.2.1)

\( B \) and \( A \) being non-negative \( m \times n \)-matrices of input and output coefficients; i.e., \( b_{ij}x_j(t) \) and \( a_{ij}x_j(t) \) are the quantities of input and output resp. of the \( i \)-th goods if the \( j \)-th production process during the \( t \)-th period is executed at an activity level \( x_j(t) \). According to supposition a) the input \( b_{ij}x_j(t) \) is absorbed at the beginning of period \( t \) and the output \( a_{ij}x_j(t) \) is available at the end of this period.

With regard to the transfer of goods between the various production processes we further introduce the following suppositions:

d) The transfer of goods between the processes, takes place simultaneously during the changing of periods.

e) Surpluses are allowed.

f) Surpluses occurring during one change of period are not available during the following changes of periods.
If no goods from without are conveyed towards or from this economy, then the latter three suppositions imply that with a given vector of initial activity levels $x(0)$, a sequence of activity levels $x(1), x(2), \ldots$ is feasible if and only if the following inequalities are satisfied:

$$Bx(1) \leq Ax(0)$$

$$Bx(t+1) - Ax(t) \leq 0, \quad t \geq 1$$

$$x(t) \geq 0, \quad t \geq 1.$$  \hspace{1cm} (1.2.2)

We observe that the conditions a) and f) appear more limiting than in reality they are. For the preservation of surpluses during a period as such, can again be formulated as a special production process.

To the system described thus far, we shall add a number of elements, whereas the conditions a) to f) will remain valid.

Firstly one may assume that goods from without are made available for the system. In this connection, for instance the factor labour might, in a certain manner, be taken into account. We assume, that this availability of goods has a content of $\alpha t^f$, for each charge of period $(t-1,t)$. In which assumption $\alpha > 0$ represents a growth factor and $f$ a non-negative m-dimensional vector. Under this extension system (1.2.2) takes the following form:

$$Bx(1) \leq \alpha t^f + Ax(0)$$

$$Bx(t+1) - Ax(t) \leq \alpha(t+1)^f, \quad t \geq 1$$

$$x(t) \geq 0, \quad t \geq 1.$$  \hspace{1cm} (1.2.3)

We now turn our attention towards the consumption aspect. We distinguish two kinds of consumption: autonomous consumption and endogenous consumption. Autonomous consumption may be interpreted as those quantities of goods which are necessary to meet the primary needs. Endogenous consumption may be interpreted as the extra.
We assume that, for each change of period \((t-1, t)\), the autonomous consumption is \(\beta g\); herein \(\beta > 0\) represents a growth factor and \(g\) a non-negative \(m\)-dimensional vector. Under this addition, system (1.2.3) takes the form of:

\[
\begin{align*}
Bx(t) + \gamma^t \beta g & = \alpha t - \beta g \cdot Ax(0) \\
Bx(t+1) - Ax(t) & \leq \alpha^{t+1} t - \beta^{t+1} E_2, \ t \geq 1; \\
x(t) & \geq 0, \ t \geq 1.
\end{align*}
\] (1.2.4)

Thus, given the initial activity levels \(x(0)\), a sequence of activity levels \(x(1), x(2), \ldots\) is feasible if and only if (1.2.4) is satisfied.

With regard to the process of endogenous consumption we introduce the following suppositions comparable with a), b) and c):

\(g\) The process of free consumption takes place in a sequence of periods of the same duration as that of the production processes.

\(h\) The process of free consumption may consist of various subprocesses. For each subprocess the input of goods is proportional to its level of activity.

\(i\) For each subprocess the proportion of input and the level of consumption activity remains the same for all periods.

The latter three suppositions are elaborated in a similar manner as the suppositions a), b) and c). Assuming that there are \(k\) subprocesses for endogenous consumption, and representing the activity levels of these subprocesses by a sequence of non-negative \(k\)-dimensional vectors \(x^c(1), x^c(2), \ldots\), then, with the help of a non-negative \(m \times k\)-matrix \(B^c\) of consumption coefficients, the corresponding quantity of input may be expressed:

\[
B^c x^c(t), \ t \geq 1.
\] (1.2.5)

Combining (1.2.4) and (1.2.5), we may conclude that, under the
conditions a) to i), with a given \( x(0) \), a sequence of activity levels \( (x(1), x^c(1)), (x(2), x^c(2)), \ldots \) is feasible if and only if

\[
\begin{align*}
Bx(1) + E^{c}x^c(1) & \leq a_1 - b_1 + A_{\infty}x(0) \\
Bx(t+1) - Ax(t) & \leq a_2^{t+1} - b_2^{t+1} + B, \quad t \geq 1 \\
x(t), x^c(t) & \geq 0, \quad t \geq 1
\end{align*}
\]

is satisfied.

We complete the introduction of engogeneous consumption by addition of a linear utility function. We shall assume that the utility of each sequence of levels of consumption activities \( x^c(1), x^c(2), \ldots, x^c(T), \ldots \) can be expressed as follows:

\[
\sum_{t=1}^{T} \pi^t p^t x^c(t)
\]

where:
- \( p \) is a non-negative \( k \)-dimensional vector and
- \( \pi \) a positive discount factor, in which the appreciation of a succeeding period is expressed in relation to the preceding period. So, generally \( \pi \) will be smaller than one.

Starting from the supposition that the economy described above does no cease to exist, the following problem arises: How many periods will the utility function (1.2.7) of a feasible sequence of activity levels \( (x(1), x^c(1)), (x(2), x^c(2)), \ldots \) have to cover for an adequate valuation of such a sequence to be obtained? Clearly, each fixation of the number of periods covered by the valuation, or differently put, fixation of the horizon, is bound to introduce a certain arbitrariness. This arbitrariness can be efficiently avoided by effectuating the valuation over an infinite number of periods. This results in the following expression:

\[
\sum_{t=1}^{\infty} \pi^t p^t x^c(t) := \lim_{T \to \infty} \sum_{t=1}^{T} \pi^t p^t x^c(t).
\]

(1.2.8)
Now, a particular difficulty may present itself. For it is very well possible that, for a number of feasible sequences of activity levels \((x(1), x^e(1)), (x(2), x^e(2)), \ldots\), the limit (1.2.8) does not exist. To illustrate this possibility, we consider the case that there is no autonomous consumption (i.e.: \(g = 0\)) and that, for certain \(x(0)\), system (1.2.6) possesses a solution of the form

\[
\begin{align*}
  x(t) &= \rho^t x^1, \\
  x^e(t) &= \rho^t x, \quad t \geq 1.
\end{align*}
\]  

(1.2.9)

For such a feasible sequence, we have:

\[
\lim_{t \to \infty} \frac{\pi^t \rho^t x^2(t)}{\rho^{\infty}} = \frac{\pi^1}{\rho^{\infty}} \frac{(\pi^t \rho^t x^2(t))}{\rho^{\infty}}, \quad t \geq 1 \]  

(1.2.10)

If \(\pi^1 \rho^t x^2 > 0\) and if \(\rho^t \geq 1\), then it appears that the sequence of numbers defined by (1.2.10) has no upper bound. In that case, the expression (1.2.6) cannot represent a sensible utility function. This difficulty can be eliminated by choosing the positive coefficient \(\pi\) so small that \(\pi^1 \rho^t < 1\).

Apart from the complication as sketched above, the optimization aspect in this economy can be roughly formulated as follows:

Given the initial intensities \(x(0)\), find a sequence of activity levels \((x(1), x^e(1)), (x(2), x^e(2)), \ldots\), which satisfies (1.2.6) and for which the limit (1.2.8) attains a maximum value.

Finally, we shall give the model consisting of the inequalities (1.2.6) and the utility function (1.2.7) and (1.2.8) a more general form.

Firstly, we write the left hand side of (1.2.6) in the less specified form:

\[
\rho^t f(t), \quad t \geq 1,
\]

in which \(\rho\) is a positive growth factor and \(f(1), f(2), \ldots\) a se-
sequence of $m_1$-dimensional vectors for which non-negative vectors $\overline{f}$ and $\overline{f}$ are supposed to exist such that

$$-\overline{f} \leq f(t) \leq \overline{f}, \quad t \geq 1. \quad (1.2.1)$$

Thus, (1.2.6) takes the form:

$$Bx(1) + B^0e^0(1) \leq \rho f(1) + Ax(0),$$

$$Bx(t+1) + B^0e^0(t+1) - Ax(t) \leq \rho x^1f(t+1), \quad t \geq 1,$$

$$x(t), x^0(t) \leq 0, \quad t \geq 1.$$

With the help of two non-negative $m_1 \times (n+k)$-matrices:

$$\overline{E} := (B, B^0)$$

$$\overline{X} := (A, 0) \quad (1.2.12)$$

this system can be written:

$$Bx(1) \leq \rho f(1) + Ax(0)$$

$$Bx(t+1) - Ax(t) \leq \rho x^1f(t+1), \quad t \geq 1,$$

$$x(t) \geq 0, \quad t \geq 1. \quad (1.2.13)$$

where $x(0), x(1), \ldots$ is a sequence of $(n+k)$-dimensional vectors, which correspond with the activity levels $(x(0), x^0(0)), (x(1), x^0(1)), \ldots$.\n
The utility functions (1.2.7) and (1.2.8) will be written in the loss specified form:

$$\sum_{t=1}^{T} \pi^0 e^0(t) x(t), \quad T \geq 1, \quad (1.2.14)$$

$$\sum_{t=1}^{\infty} \pi^0 e^0(t) x(t), \quad (1.2.15)$$
in which \( \overline{v}(1), \overline{v}(2), \ldots \) is a sequence of \( n \)-dimensional vectors for which non-negative vectors \( \overline{v} \) and \( \overline{\bar{v}} \) are supposed to exist such that:

\[
-\overline{v} \leq \overline{\bar{v}}(t) \leq \overline{v} \quad , \quad t \geq 1. \quad (1.2.16)
\]

Since negative components are permitted in the vectors \( \overline{v}(1), \overline{v}(2), \ldots \) we shall use the more general term objective functions, for the expressions (1.2.14) and (1.2.15).

Growth model I, consisting of the inequalities (1.2.13) and the objective functions (1.2.14) and (1.2.15), will be the point of departure for the growth models now to be discussed.

1.3 Growth model II.

We now turn our attention towards durable goods, or briefly, durables. In comparison with the goods of model I, further to be called non-durables, the durable goods possess some characteristic properties specified as follows:

a) The durables which are necessary for a production process, will be adopted at the beginning of a period and will become free at the end of the period.

b) The quantity of durables which are used in a production process, is proportional to the activity level of this process.

c) The proportion between the durables used in a production process, and the level of activity of the process, is the same for all periods.

The formation and the process of obsolescence of all sorts of durables will be specified as follows:

d) All durables are formed timelessly out of the non-durables on the moments of period change.

e) The quantity of non-durables used for the formation of durables is proportional to the quantity of these goods.
f) The proportions of the quantities mentioned at e) are constant for all periods.

g) All durables have a finite durability. The curve of obsolescence is the same for all periods. Moreover, durables cannot change in type.

h) There is no exogenous supply of removal of capacity goods.

The transfer of durables is supposed to be of the same nature as specified in 1.2.a, e, f.

First we elaborate the suppositions 1.3-d, g. For the sake of simplicity, we here assume that the durability of durable goods is three periods at most. Let \( L \) be the number of sorts of durables, then, during each period \( t \), this economy contains the following durables:

- durables formed at the moment of period change \((t-1,t)\); the quantity of these is expressed by a non-negative \( L \)-dimensional vector \( z(t;0) \),
- durables formed at the moment of period change \((t-2,t-1)\); represented by a non-negative \( L \)-dimensional vector \( z(t;1) \),
- durables formed at the moment of period change \((t-3,t-2)\); represented by a non-negative \( L \)-dimensional vector \( z(t;2) \).

With the help of two non-negative \( L \times L \)-dimensional matrices \( \gamma(1) \) and \( \gamma(2) \), for every period \( t \), the actual quantity of durables (via. 1.3-g) can be expressed by

\[
z(t;0) + \gamma(1) z(t;1) + \gamma(2) z(t;2),
\]

(1.3.1)

The suppositions 1.2-a, f and the definition of the vectors \( z(t;0), z(t;1), z(t;2), t \geq 0 \), imply the inequalities:

\[
\begin{align*}
z(t+1;1) &\leq z(t;0) \\
z(t+1;2) &\leq z(t;1),
\end{align*}
\]

(1.3.2)
For the elaboration of the suppositions 1.3-a to 1.3-I, we start from the inequalities (1.2.3) of growth model I:

\[
\begin{align*}
Sx(1) & \leq \sigma f(1) + Ax(0) \\
Sx(t+1) - Ax(t) & \leq \sigma x(t) f(t+1) , \quad t \geq 1 , \\
\bar{x}(t) & \geq 0 , \quad t \geq 1 ,
\end{align*}
\]

with \( n \) types of non-durables and \( n = n + k \) processes.

With the help of a \( L \times n \) matrix \( C \), the use of durables for every sequence of activity levels \( \bar{x}(1), \bar{x}(2), \ldots \), can be expressed by:

\[
C\bar{x}(t) , \quad t \geq 1 .
\]

(1.3.4)

With the help of a non-negative matrix \( D \) the volume of non-durables used for the formation of durables can be expressed by:

\[
Dz(t;0) , \quad t \geq 1 .
\]

(1.3.5)

The supposition 1.2-a,d,g and 1.3-a,d imply that for the first period we may join the expressions (1.3.1) to (1.3.5) in the following inequalities:

\[
\begin{align*}
Rz(1) + 3z(1;0) - \sigma z(1;0) + \bar{x}(0) & \leq 0 \\
C\bar{x}(1) - z(1;0) - \gamma(1)z(1;1) - \gamma(2)z(1;2) & \leq 0 \\
z(1;1) & \leq z(0;0) \\
z(1;2) & \leq z(0;1) \\
\bar{x}(1), z(1;0), z(1;1), z(1;2) & \geq 0
\end{align*}
\]

(1.3.6)

and for the succeeding periods:
\[ Bx(t+1) + Bz(t+1;0) = -A(x(t) \leq \rho^{t+1} T(t+1)) \]

\[ Cx(t+1) + z(t+1;0) - \gamma_1 z(t+1;1) - \gamma_2 z(t+1;2) \leq 0 \]

\[ z(t+1;1) - z(t;0) \leq 0 \quad ; \quad t \geq 1 \]

\[ z(t+1;2) - z(t;1) \leq 0 \]

\[ \tilde{z}(t), z(t;0), z(t;1), z(t;2) \geq 0 \]

(1.3.7)

Thus, given \( (x(0), z(0;0), z(0;1)) \), a sequence \( (x(t), z(t;0), z(t;1), z(t;2)), \ t = 1, 2, \ldots \) is feasible if and only if (1.3.6) and (1.3.7) are satisfied.

With the help of the \( (n_1 + L + L^2) \times (n_1 + L + L^2) \)-matrices

\[ B := \left[ \begin{array}{cccc} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right] \]

\[ C := \left[ \begin{array}{cccc} -1 & \gamma_1 & \gamma_2 \\ 0 & 0 & 0 \end{array} \right] \]

\[ A := \left[ \begin{array}{cccc} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array} \right] \quad (1.2.8) \]

and with the help of the sequence of \( (n_1 + L + L^2) \)-dimensional vectors defined by

\[ \tilde{z}(t) := \left[ \begin{array}{c} \tilde{z}(t) \\ 0 \\ 0 \end{array} \right] \quad t \geq 1. \quad (1.3.9) \]

the inequalities (1.3.7) can be written:

\[ \tilde{z}(1) \leq \rho \tilde{z}(1) + \tilde{z}(0) \]

\[ \tilde{z}(t+1) - \tilde{z}(t) \leq \rho^{t+1} T(t+1), \ t \geq 1 \]

\[ \tilde{z}(t) \geq 0 \quad , \quad t \geq 1. \quad (1.3.10) \]
where \( \hat{x}(0), \hat{x}(1), \ldots \) is a sequence of \((n_1 + n_2 + L + 1)\)-dimensional vectors which corresponds with the sequence \((x(t), x(t; 0), x(t; 1), x(t; 2)), t = 0, 1, 2, \ldots\) appearing in (1.3.6) and (1.3.7). So, the vectors \( \hat{x}(t), t \geq 0 \) represent quantities of a different nature. Therefore, we shall use the more general term state vectors.

When we define the sequence of \((n_1 + n_2 + L + 1)\)-dimensional vectors \( \bar{\pi}(1), \bar{\pi}(2), \ldots \) by:

\[
\bar{\pi}(t) := \begin{bmatrix} p(t) \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad t \geq 1
\]

\( \bar{\pi}(1), \bar{\pi}(2), \ldots \) being the sequence of vectors of the objective functions (1.2.14) and (1.2.15), then the corresponding objective functions of a sequence \( \hat{x}(1), \hat{x}(2), \ldots \) which satisfies (1.3.9), can be written:

\[
\begin{align*}
\bar{\sum}_{t=1}^{T} \bar{\pi}(t) & \hat{x}(t), \quad T > 1, \\
\bar{\sum}_{t=1}^{m} \bar{\pi}(t) & \hat{x}(t),
\end{align*}
\]

Clearly, the optimization aspect may be formulated in the same manner as in growth model I.

The system of inequalities (1.3.10) together with the objective functions (1.3.12) and (1.3.13) form growth model II. We observe that this model has the same form as growth model I. Further we observe that the definitions (1.3.8) and (1.3.9) imply the following:

1) Each row vector \( \mathbf{y}_{i} \) of matrix \( \mathbf{y} \) which contains one or more negative components, corresponds with a non-negative row.
vector $\hat{z}$ of matrix $\hat{A}$ and with non-negative components $\hat{y}(t)$ of the vectors $\hat{x}(1), \hat{x}(2), \ldots $.

j) Matrix $\hat{A}$ contains no negative components.

1.5 Growth model III.

Now we shall add import and export facilities. These are specified as follows:

a) The processes of import and export are executed in the same sequence of periods as the production processes. The quantity of goods to be imported and exported is determined at the beginning of a period; the actual import and export takes place timelessly at the end of the period.

b) The quantity of goods which are used for the effectuation of import and export (for instance transport capacity) is taken up at the beginning of a period, and is proportional to the quantity of imported and exported goods.

c) Import and export take place at fixed prices. Import prices are not lower than export prices.

d) The reserve of payments at the end of a period is composed of reserve of payments at the end of the proceeding period, multiplied by an interest factor, increased by the value of the export and decreased by the value of the import at the end of the period.

e) The reserve of payments cannot be negative.

f) The proportion of the quantities mentioned at b), the import and export prices and the interest factor appearing in d) are the same for all periods.

We take growth model II as the point of departure:

\[
\begin{align*}
\hat{x}(1) & \leq \hat{y}(1) \cdot \hat{x}(0) \\
\hat{x}(t+1) - \hat{x}(t) & \leq \hat{y}(t) \cdot (t-1), \quad t \geq 1 \\
\hat{x}(t) & \geq 0, \quad t \geq 1
\end{align*}
\]

(1.4.1)
where:
- $\tilde{x}(0), \tilde{\tilde{x}}(1), \ldots$ and $\tilde{y}(1), \tilde{y}(2), \ldots$ are sequences of $n_2$ and $n_2$ dimensional vectors ($m_2 = n_1 + 1 + l_1 + l_2$ and $n_2 = n_1 + 1 + l_1$).
- $\tilde{x}$ and $\tilde{y}$ are $m_2 \times m_2$ matrices which possess the properties (1.3-i) and (1.3-j).

For the sake of simplicity, we shall here assume that all types of goods can be imported and exported; the quantities will be denoted by the sequences of $m_2$-dimensional vectors $x^i(0), x^i(1), \ldots$ and $x^e(0), x^e(1), \ldots$, $x^i(t)$ being the quantity of imported goods at the end of period $t$ and $x^e(t)$ the export quantity.

Supposition 1.4-b implies that the quantity of goods used for the effectuation of import and export can be expressed by:

$$
\begin{align*}
&x^i(t), \quad t \geq 0, \\
&x^e(t), \quad t \geq 0
\end{align*}
$$

(1.4.2)

where $x^i$ and $x^e$ are non-negative $m_2 \times m_2$ matrices.

Supposition 1.4-a implies that (1.4.1) and (1.4.2) can be combined into the system:

$$
\begin{align*}
&\hat{y}(0) + x^i(1) \cdot c_1 x^e(1) \leq \hat{y}(1) + \hat{y}(0) + x^i(1) - x^b(0) \\
&\tilde{y}(t+1) + x^i(t+1) \cdot c_2 x^e(t+1) - \tilde{y}(t+1) - x^i(t) + x^b(t) \leq \tilde{y}(t+1) + x^i(t) - x^b(t), \quad t \geq 1 \\
&\tilde{x}(t), x^i(t), x^e(t) \geq 0, \quad t \geq 0
\end{align*}
$$

(1.4.3)

The suppositions 1.4-c to 1.4-f are elaborated as follows. The reserve of payment at the end of the periods $t = 0, 1, 2, \ldots$ can be represented by a sequence of non-negative numbers $r(0), r(1), \ldots$. Denoting the import and export by non-negative $m_2$-dimensional vectors $q^i$ and $q^e$, and the interest factor by a number $a > 1$, then supposition 1.4-a gives rise to the following inequalities:
Now, we may conclude that in such an economy, given the initial quantities \((\bar{y}(0), r(0), x^d(0), x^e(0))\), a sequence
\((\bar{y}(1), r(1), x^d(1), x^e(1)), (\bar{y}(2), r(2), x^d(2), x^e(2)), \ldots\) is feasible if and only if simultaneously the inequalities (1.4.3) and (1.4.4) are satisfied.

With the help of the \((n_2 + 1) \times (n_2 + 1)\) matrices
\[
\mathbf{P} := \begin{bmatrix} \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \end{bmatrix}, \quad \mathbf{Q} := \begin{bmatrix} \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \end{bmatrix}, \quad (1.4.5)
\]
and with the help of a sequence of \((n_2 + 1)\)-dimensional vectors \(\mathbf{z}^{(1)}, \mathbf{z}^{(2)}, \ldots\) defined by:
\[
\mathbf{z}^{(t)} := \begin{bmatrix} \mathbf{f}(t) \\ \mathbf{0} \end{bmatrix}, \quad t \geq 1, \quad (1.4.6)
\]
the systems (1.4.3) and (1.4.4) may be combined in the system:
\[
\begin{align*}
\mathbf{z}^{(1)} & \leq \mathbf{p} \mathbf{z}^{(1)} + \mathbf{g}(0), \\
\mathbf{z}^{(t+1)} - \mathbf{g}(t+1) & \leq \mathbf{p}^{t+1} \mathbf{z}^{(t+1)}, \quad t \geq 1, \\
\mathbf{g}(t) & \geq 0, \quad t \geq 1
\end{align*} \quad (1.4.7)
\]
where \(\mathbf{g}(0), \mathbf{g}(1), \ldots\) is a sequence of \((n_2 + 1)\)-dimensional vectors which corresponds with the sequence
\((\bar{y}(0), r(0), x^d(0), x^e(0)), (\bar{y}(1), r(1), x^d(1), x^e(1)), \ldots\).

When we define the sequence of \((n_2 + 1)\)-dimensional vectors
\begin{align}
\tilde{p}(t) = \begin{cases}
0 & t < 1, \\
0 & t \geq 1,
\end{cases}
\end{align}

\tilde{y}(1), \tilde{y}(2), \ldots \text{ being the sequence of vectors of the objective functions (1.3.12) and (1.3.13), then the corresponding objective functions of a sequence } \chi(1), \chi(2), \ldots \text{ which satisfies (1.4.7), can be written}

\begin{align}
\frac{1}{\sum_{t=1}^{\infty} \pi^2 \tilde{p}(t)^{T} \chi(t)}, & \quad T \geq 1, \\
\frac{1}{\sum_{t=1}^{\infty} \pi^2 \tilde{p}(t)^{T} \chi(t)}, & \quad T \geq 1,
\end{align}

System (1.4.7) together with the objective functions (1.4.9) and (1.4.10) form growth model III. This model has the same form of growth models I and II.

Clearly, the definitions (1.4.5) and (1.4.8) and property 1.3-j imply that growth model III possesses the following property:

1) Each column vector \( \tilde{p}_{i} \) of matrix \( \tilde{p} \) which contains one or more negative components, corresponds with a non-negative column vector \( p_{i,j} \) of matrix \( p \), and with non-positive components \( p_{i,j} \) of the vectors \( p(1), p(2), \ldots \).

1.5 Growth model IV.

Now, the suppositions 1.2-c, 1.3-c, f and 1.4-q will be weakened by introduction of the possibility of cyclic change, as for instance caused by the influence of the seasons. For the sake of simplicity, we here suppose that the cycle consists of two phases: the first and the second half of the year. We put model III as the point of departure.
The state vectors of model III will be represented by a sequence of pairs of non-negative $m_3$-dimensional vectors $(x^1(t), x^2(t)), (x^1(t+1), x^2(t+1)), \ldots$, where $x^i(t)$ represents the first half of the $t$-th year and $x^i(t)$ the second. Now model III can be written:

\[
\begin{align*}
B^{(1)} x^1(t) &\leq \rho f^1(t) + A^{(2)} x^2(t), \\
B^{(2)} x^2(t) &\leq \rho f^2(t), \\
B^{(1)} x^1(t+1) - A^{(1)} x^1(t) &\leq \rho t^{f^1(t+1)}, \\
B^{(2)} x^2(t+1) - A^{(1)} x^1(t+1) &\leq \rho t^{f^2(t+1)} - \rho t^{f^2(t+1)}, \\
x^1(t), x^2(t) &\geq 0, \quad t \geq 1
\end{align*}
\]

where, $A^{(1)}$, $A^{(2)}$, $B^{(1)}$, and $B^{(2)}$ are $m_3 \times m_3$-matrices and $f^1(t), f^2(t), \rho t^{f^1(t+1)}, \rho t^{f^2(t+1)}$ are sequences of $m_3$-dimensional vectors.

When we define the $(m_3 \times m_3) \times (m_3 + m_3)$-matrices

\[
B := \begin{bmatrix} B^{(1)} & 0 \\ -A^{(1)} & B^{(2)} \end{bmatrix}, \quad A := \begin{bmatrix} 0 & A^{(2)} \\ 0 & 0 \end{bmatrix},
\]

and the sequence of $(m_3 + m_3)$-dimensional vectors

\[
\begin{bmatrix} f^1(t) \\ f^2(t) \end{bmatrix}, \quad t \geq 1,
\]

then system (1.5.1) can be written:

\[
\begin{align*}
B x^1(t) &\leq \rho f^1(t) + A x^2(t), \\
B x(t+1) - A x(t) &\leq \rho t^{f^1(t+1)}, \quad t \geq 1
\end{align*}
\]
where \(X(0), X(1), \ldots\) is a sequence of \((n_1 + n_2)\)-dimensional vectors which corresponds with a sequence \((x^1(0), x^2(0)), (x^1(1), x^2(1)), \ldots\) satisfying (1.3.1).

Let \((p^1(1), p^2(1)), (p^1(2), p^2(2)), \ldots\) be the vectors of corresponding objective functions (1.4.9) and (1.4.10). When we define

\[
\tilde{z}(t) := \begin{bmatrix} p^1(t) \\ p^2(t) \end{bmatrix}, \\
 t \geq 1,
\]

then the corresponding objective function for sequences \(\tilde{x}(1), \tilde{x}(2), \ldots\) satisfying (1.3.5), can be written:

\[
\sum_{t=1}^{T} \tilde{z}(t)'x(t), \quad T \geq 1,
\]

\[
= \sum_{t=1}^{T} \tilde{w}(t)'\tilde{x}(t), \quad T \geq 1.
\]

Thus, we find again that growth model IV, consisting of (1.3.4), (1.3.6), and (1.3.7), has the same form as the growth models I to III. Moreover, the definitions (1.3.2) and (1.3.5) and property 1.4-g imply:

Each column vector \(a_{ij}\) of matrix \(A\) which contains one or more negative components, corresponds with a non-negative column vector \(b_{ij}\) of matrix \(B\) and with non-positive components \(z_{ij}(t)\) of the vectors \(z(1), z(2), \ldots\).

1.6 The linear programming problem over an infinite horizon.

It appears that all growth models I to IV give rise to a linear programming problem consisting of the inequalities:
\[ Bx(1) \leq p(f(1) + Ax(0)) \]
\[ Bx(t+1) - Ax(t) \leq p^{t+1} f(t+1), \quad t \geq 1 \]
\[ x(t) \geq 0, \quad t \geq 1 \]

and an objective function

\[ \max_{\sum} \sum_{n} p(t) F(x(t)), \quad t = 1 \]

(1.6.2)

to be maximized over the \( n \)-dimensional vectors \( x(1), x(2), \ldots \), which satisfy (1.6.1). Herein:
- \( A \) and \( B \) are \( m \times n \) matrices.
- \( f(1), f(2), \ldots \) is a sequence of \( m \)-dimensional vectors for which \( m \)-dimensional vectors \( f \) and \( \overline{f} \) exist, such that:
  \[ -\overline{f} \leq f(t) \leq \overline{f}, \quad t \geq 1 \]

(1.6.3)
- \( p(1), p(2), \ldots \) is a sequence of \( n \)-dimensional vectors for which \( n \)-dimensional vectors \( p \) and \( \overline{p} \) exist, such that:
  \[ -\overline{p} \leq p(t) \leq \overline{p}, \quad t \geq 1 \]

(1.6.4)
- \( p \) and \( \overline{p} \) are positive coefficients.
- \( x(0) \) is a given initial \( n \)-dimensional vector, which is non-negative.

With respect to the matrices \( A \) and \( B \) and the sequences of vectors \( f(1), f(2), \ldots \) and \( p(1), p(2), \ldots \), it is found that, in these growth models, at least one of the following conditions is satisfied:

a) Each row vector \( b_{k} \) of matrix \( B \) which contains one or more negative components, corresponds with a non-negative row vector \( a_{l} \) of matrix \( A \), and with non-negative components \( f_{k}(t) \) of the vectors \( f(1), f(2), \ldots \).

b) Each column vector \( a_{j} \) of matrix \( A \) which contains one or more
negative components, corresponds with a non-negative column vector \( b_j \) of matrix \( B \), and with non-positive components \( p_j(t) \) of the vectors \( p(t) \), \( p(2), \ldots \).

In this study we investigate a linear programming problem which possesses the structure as sketched above. In this investigation another linear programming problem arises naturally. This problem consists of the linear inequalities:

\[
B'\mathbf{u}(t) - A'\mathbf{u}(t+1) \geq \sum_{p(t)} p(t), \quad t \geq 1
\]

\[
\mathbf{u}(t) \geq 0, \quad t \geq 1
\]

(1.6.2)

and the objective function

\[
\mathbf{x}(0)'A'\mathbf{u}(1) + \sum_{t=1}^{\infty} p(t)'\mathbf{u}(t)
\]

(1.6.6)

to be minimized over the \( m \)-dimensional vectors \( u(1), u(2), \ldots \), which satisfy (1.6.2).

The quantities appearing in this problem are the same as that of the first problem.

It will be shown later, that the coherence between both problems is of the same nature as the coherence between two linear programming problems over a finite horizon, which are dual with respect to each other. This offers the possibility ( ) to interpret a sequence of vectors \( u(1), u(2), \ldots \), which satisfies (1.6.4) and for which (1.6.5) attains its minimal value, as a sequence of prices, i.e., \( u_i(t) \) represents the price of the \( i \)-th goods at the moment of the period change \( (t-1,t) \). That means that, in the context of growth models I to IV, the expression

\[
b_j'\mathbf{u}(t) - a_j'\mathbf{u}(t+1) = e_jp(t)
\]

(1.6.7)

may be taken as the netto costs of the \( j \)-th process per unit of
intensity in the \( t \)-th period. Thus, in this manner, we may interpret a sequence of vectors \( u(1), u(2), \ldots \), which satisfies (1.6.4) as a sequence of prices such that in none of the periods any process yields netto benefits. The expression (1.6.6) might be taken as the value of the exogeneous goods \( x(0), \rho^T(1), \rho^T(2), \rho^T(3), \ldots \), at these prices.

A further interpretation of the conditions a) and b) can be given as follows. It will be shown (3.2) that condition a) implies that all sequences \( x(1), x(2), \ldots \), satisfying (1.6.1) for some initial vector \( x(0) \), also satisfying:

\[
Ax(t) + \rho^T(t+1) \geq 0 \quad t \geq 1.
\]  

(1.6.8)

This means that for every period \( t \geq 1 \) the expression \( Ax(t) + \rho^T(t+1) \) may be interpreted as the quantity of goods available for the processes at the beginning of period \( t+1 \). In that respect we can say that in such an economy all goods are transferred from a preceding period to the succeeding period. For that reason we call a system (1.6.1) directed, if it satisfies condition a).

In a similar way it appears that condition b) implies that all sequences \( u(1), u(2), \ldots \) satisfying (1.6.5), also satisfy:

\[
B'u(t) - \rho^T(t) \geq 0, \quad t \geq 1.
\]  

(1.6.9)

Since, for all periods \( t \geq 1 \), the value of the expression \( b_j'u(t) - \rho^T_j(t) \) is non-negative, and since the vector \( u(t) \) may be taken as the prices of the goods at the beginning of period \( t \), the expression \( b_j'u(t) - \rho^T_j(t) \) may be interpreted as the costs per unit of activity level for the \( j \)-th process in period \( t \). Moreover, since (1.6.6) may be interpreted as the netto costs, one might say that the costs \( b_j'u(t) - \rho^T_j(t) \) are always accountable at the end of period \( t \). Therefore, we shall call a system (1.6.5) directed, if it satisfies condition b).
With respect to the optimization aspect of the two linear programming problems described above, a sequence of \(n\)-dimensional vectors \(x(1), x(2), \ldots\), will be called an optimal solution of the first problem if this sequence satisfies (1.6.1) and if no sequence of \(n\)-dimensional vectors \(x(1), x(2), \ldots\) exists, which satisfies (1.6.1) as well as

\[
\sum_{t=1}^{T} p(t) x(t) \geq \sum_{t=1}^{T} p(t) x(t) - \epsilon, \quad T \geq T^*,
\]

to some positive number \(\epsilon\) and some period \(T^* \geq 1\).

In a similar manner, a sequence of \(m\)-dimensional vectors \(\bar{x}(1), \bar{x}(2), \ldots\) will be called an optimal solution of the second problem if this sequence satisfies (1.6.5) and if no sequence of \(m\)-dimensional vectors \(u(1), u(2), \ldots\) exists, which satisfies (1.6.5) as well as

\[
\sum_{t=1}^{T} f(t) u(t) \leq \sum_{t=1}^{T} f(t) u(t) - \epsilon, \quad T \geq T^*,
\]

for some positive number \(\epsilon\) and some period \(T^* \geq 1\).

The most important questions which are dealt with this study are the following:

- When do exist sequences of \(n\)-dimensional vectors \(x(1), x(2), \ldots\) satisfying (1.6.1), and when do exist sequences of \(m\)-dimensional vectors \(u(1), u(2), \ldots\) satisfying (1.6.5)?

- When do optimal solutions exist for the first and the second problem?

- What is the asymptotic behavior for \(t \to \infty\) of optimal solutions \(x(1), x(2), \ldots, x(t), \ldots\) and \(u(1), u(2), \ldots, u(t), \ldots\) of the first and the second linear programming problem resp.?
1.7 Summary of the most important results.

Presumed that at least one of the conditions 1.6-a or 1.6-b is satisfied, it appears that the linear programming problem consisting of (1.6.1), (1.6.2) and of (1.6.3), (1.6.4) are sensible only if \( \rho \sigma < 1 \). In that case, we found that, under certain conditions which are somewhat stronger than the assumption that both problems possess feasible solutions, the problems both possess optimal solutions.

It appears that the coherence between both problems is of a similar nature as the coherence between two linear programming problems in a finite dimensional space which are dual with respect to each other.

The most advanced results are obtained when the sequences of vectors \( f(1), f(2), \ldots \) and \( p(1), p(2), \ldots \), are supposed to be constant ever since some period \( K \geq 1 \). Then, under some additional conditions, it can be shown that all optimal solutions \( \hat{x}(1), \hat{x}(2), \ldots \) and \( \hat{u}(1), \hat{u}(2), \ldots \) of the first and the second problem converge to certain fixed vectors \( \hat{x} \) and \( \hat{u} \) in the following manner:

\[
\lim_{t \to \infty} (\frac{1}{t})^t \hat{x}(t) = \hat{x}.
\]

\[
\lim_{t \to \infty} (\frac{1}{t})^t \hat{u}(t) = \hat{u}.
\]

This property offers the possibility to construct a linear programming problem over a finite horizon from which all optimal solutions of the original infinite horizon can be found.
2. MATHEMATICAL FORMULATION OF THE LINEAR PROGRAMMING SYSTEM.

2.1 Introduction.
First, we introduce a number of general concepts and notations. With the help of these, the formulation of the linear programming system is given, which forms the central theme of this study. Finally, some concepts will be introduced with respect to the structure of this linear programming problem.

2.2 $l_1$- and $l_\infty$-space.
The (real) $l_1$- and $l_\infty$-spaces are particular specimens of the so-called $l_\alpha$-spaces ($\alpha$ is a constant). They are defined as follows.

The $l_1$-space is a vector space consisting of the sequences of (real) numbers $\{x_i\}_{i=1}^m$ for which

$$\sum_{i=1}^{m} |x_i| < \infty. \quad (2.2.1)$$

The norm of an element $x := \{x_i\}_{i=1}^m \in l_1$ is defined by

$$\|x\|_1 := \sum_{i=1}^{m} |x_i|. \quad (2.2.2)$$

The $l_\infty$-space is a vector space consisting of the sequences of (real) numbers $\{x_i\}_{i=1}^m$ for which

$$\sup_{i} |x_i| < \infty. \quad (2.2.3)$$

The norm of an element $x := \{x_i\}_{i=1}^m \in l_\infty$ is defined by

$$\|x\|_\infty := \sup_{i} |x_i|. \quad (2.2.4)$$

The $l_1$- and $l_\infty$-norm may be introduced in a similar way for finite dimensional vector spaces.
The $l_1^k$- and $l_\infty^k$-spaces considered by us possess a special structure which can be described in the following manner.

Consider the sequences of vectors $(x(t))_t^n$ in a $k$-dimensional real vector space $R^k$. The set of such sequences may be taken as an $\infty$-dimensional vector space and denoted by $l_\infty^k$. This leads to the following formal definition:

$$l_1^k:=\{x:=(x(t))_t^n|x(t)\in R^k, t\in T\}.$$  \hfill (2.2.5)

Now we wish to introduce the $l_1^k$-space to be defined as the set of vectors in $l_1^k$ for which

$$\sum_{t=1}^\infty \sum_{i=1}^k |x_i(t)| < \infty,$$  \hfill (2.2.6)

with the norm:

$$\|x\|_1 := \sum_{t=1}^\infty \sum_{i=1}^k |x_i(t)|.$$  \hfill (2.2.7)

In a similar way we define the $l_\infty^k$-space as the set of vectors in $l_\infty^k$ for which

$$\sup_{t} \max_{i} |x_i(t)| < \infty.$$  \hfill (2.2.8)

The norm of this space is defined by

$$\|x\|_\infty := \sup_{t} \max_{i} |x_i(t)|.$$  \hfill (2.2.9)

It appears that every $l_1^k$- or $l_\infty^k$-space may be considered as an $l_1$- or $l_\infty$-space resp. For if $x:=(x(t))_t^n \in l_1^k$, then the sequence $(x_{(t)})_t^n$ defined by

$$x_{(t)} := x_{(t)}(t)=\sum_{i=1}^k x_i(t),$$  \hfill (2.2.10)

is a vector of $l_1$ with the same norm. The other way round, with the help of an opposite process every vector of $l_1$ may be identified with a vector of $l_1^k$ possessing the same norm.
A similar relation may be constructed between $l_0^T$ and $l_0^k$. This means that all properties of the $l_1^T$ and $l_0^T$-space simply can be transferred to the $l_1^k$ and $l_0^T$-spaces resp.

We shall also use the $l_1^T$- and $l_0^T$-norm for vectors $x \in l_0^k$ in another way, namely:

$$\|x\|_{l_1^T} = \sum_{t=0}^{T} \sum_{i=1}^{k} |x_i(t)|, \quad T \geq 1.$$  \hspace{1cm} (2.2.11)

$$\|x\|_{l_0^T} = \sup_{T \geq 2} \max_{\tau \leq T} |x_\tau(t)|, \quad T \geq 1.$$  \hspace{1cm} (2.2.12)

Finally, we define the positive cone of $l_1^k$, $l_0^k$ and $l_0^T$ by:

$$l_1^k = \{ (x(t))_{k} \in l_0^k | x(t) \geq 0, \quad t \geq 1 \},$$  \hspace{1cm} (2.2.13)

$$l_0^k = l_1^k \cap l_0^k,$$  \hspace{1cm} (2.2.14)

$$l_0^T = l_0^k \cap l_0^T.$$  \hspace{1cm} (2.2.15)

A well known property of the $l_1^T$-space is that the positive cone defined in this manner does not have an interior point.

However, the interior of $l_0^T$ is not empty and is defined by

$$\text{Int}(l_0^T) = \left\{ (x(t))_{k} \in l_0^k \mid x_i(t) \geq 0, \quad i=1, \ldots, k, \quad t \geq 1, \right\} \text{ for some } \epsilon > 0.$$  \hspace{1cm} (2.2.16)

2.3 The $\sigma$-transform of $x \in l_0^k$.

It is easy to see that for every positive scalar $\sigma$, the expression

$$x_\sigma = \sigma x(t);_{l_0^k}$$  \hspace{1cm} (2.3.1)
represents a one-to-one mapping of $1^k$ onto itself. This transformation which will be used frequently, will be indicated by the term $\alpha$-transformation ($\alpha$).

The coefficient of transformation $\alpha$ will ever be positive. The image $x_{\alpha}$ of $x \in 1^k$ generated by this transformation will be called the $\alpha$-transform of $x$.

In connection with this transformation we introduce the following concept: a vector $x \in 1^k$ is called $\alpha$-dominated if

$$x_{\alpha} \in 1^k.$$  \hspace{1cm} (2.3.2)

This is equivalent with the condition that a positive number $M$ exists such that

$$|x(t)| \leq \alpha^N, \quad t \geq 1.$$  \hspace{1cm} (2.3.3)

So, in this prospect the sequence of numbers $\{x(t)\}_{t=1}^{\infty}$ is dominated by $\alpha^N$, $\{t\}$.

2.4 Linear functionals.

With the help of a vector $y \in 1^k$, a sequence of numbers can be joined to every $x \in 1^k$ in the following manner:

$$<y,x> := \sum_{t=1}^{\infty} y(t)x(t), \quad t \geq 1.$$  \hspace{1cm} (2.4.1)

If such a sequence converges, the limit will be denoted by

$$<y,x>_\infty := \lim_{T \to \infty} <y,x>_T.$$  \hspace{1cm} (2.4.2)

The expression (2.4.1) and (2.4.2) may be taken as linear functionals on $1^k$. It is well known that for every $x \in 1^k$ and $y \in 1^k$ the sequence $\{<y,x>_T\}_{T=1}^{\infty}$ converges.

(\pi) In the context of this investigation confusion with the well known concept of $z$-transformation seems to be excluded.
This implies that for every \( y \in \mathbb{R}^k \), \( \langle y, x \rangle \) is a bounded (and, so a continuous) linear functional on \( \mathbb{R}^k \), and in the same manner, that for every \( y \in \mathbb{R}^k \), \( \langle y, x \rangle \) is a bounded linear functional on \( \mathbb{R}^k \).

2.3 Formulation of the linear programming system.

Now we shall give a formal definition of the growth model as described in §1.2 to §1.5. To this end we consider solutions \( x \in \mathbb{R}^n \) of the system of linear inequalities

\[
\begin{align*}
Bx(1) & \leq D^0t + Ax(0) \\
Bx(t+1) - Ax(t) & \leq D^t + \bar{c}(t+1), t \geq 1
\end{align*}
\]

where
- \( A \) and \( B \) are \( n \times n \) matrices,
- \( f = \{f(t)\}_t^\infty \in \mathbb{R}^n \),
- \( x(0) \in \mathbb{R}^n \) is the initial vector, always supposed to be non-negative,
- \( c \) is a positive scalar.

In connection with the economical background we shall term the numbers \( 0, 1, 2, \ldots \) used in the context of (2.3.1) as periods. Unless otherwise indicated, the initial vector \( x(0) \) is supposed to be a fixed given quantity.

By introduction of so called slack variables \( y = \{y(t)\}_t^\infty \in \mathbb{R}^m \), the system (2.3.1) can be converted into the system of linear equalities:

\[
\begin{align*}
Bx(1) + y(1) & = D^0t + Ax(0) \\
Bx(t+1) - Ax(t) + y(t+1) & = D^t + \bar{c}(t+1), t \geq 1
\end{align*}
\]

The systems (2.3.1) and (2.3.2) are equivalent and from now on, will be treated without distinction.
Now we shall consider for every \( x \in l_+^n \) the linear functionals

\[
\langle p, x \rangle_T := \sum_{t=1}^T x^T p(t) x(t), \quad T \geq 1,
\]

(2.5.3)

where \( p \in l_+^n \) and \( T \) is a positive scalar.

System (2.5.1) or (2.5.2), together with the linear functionals (2.5.3) will be analysed simultaneously with another system already mentioned in chapter I. In mathematical respect these systems are related by a so called duality-relation. This relation will be pointed out later and in the first instance illustrated in §2.7. Adopting the common nomenclature of the theory of linear programming in a finite dimensional space, we shall call the system (2.5.1) or (2.5.2) together with the linear functionals (2.5.3) the primal system and the system to be formulated now, the dual system. The whole consisting of the primal and dual system will be indicated by the term linear programming system or LP-system.

In the dual system we consider vectors \( u \in l_+^n \) satisfying

\[
B' u(t) - A' u(t) = \sum_{t=1}^T p(t), \quad t \geq 1,
\]

(2.5.4)

or formulated as a system of linear equalities, we consider vectors \( (u,v) \in l_+^n \times l_+^n \) satisfying

\[
B' u(t) - A' u(t) = \sum_{t=1}^T p(t), \quad t \geq 1,
\]

(2.5.5)

where \( A' \) and \( B' \) are the transposed matrices of (2.5.1), while \( p = (p(t))_1 \) and \( w \in \mathbb{R} \) correspond with (2.5.3).

With a fixed initial vector \( x(0) \) we further consider for all vectors \( u \in l_+^n \) or \( (u,v) \in l_+^n \times l_+^n \) satisfying (2.5.4), (2.5.5) resp. the linear functionals

\[
\sum_{t=1}^T x(0) A' u(t) + \sum_{t=1}^T p(t) x(t) u(t), \quad T \geq 1
\]

(2.5.6)
where \( f_1, f_1 \leq f(t) \leq f_1 \) and \( p > 0 \) are quantities already introduced in the primal system.

Denoting the sequence of vectors \( \{ f(t) \}_{t=1}^{\infty} \) by \( \mathbf{f}^0 = (f_1, f_2, \ldots) \), the linear functionals of (2.5-6) can be written

\[
<\mathbf{f}^0, \mathbf{u}> = \sum_{t=1}^{\infty} p_t f_1 u(t), \quad T \geq 1.
\]

(2.5-7)

The systems (2.5-4) or (2.5-6), combined with (2.5-7), form the dual system.

We wish to introduce some terms frequently appearing in this investigation.

The LP-system is called:

- **primal feasible** (P-feasible) when system (2.5-1) possesses a solution \( x \in I^m_1 \); this solution \( x \) or a solution \( (x, y) \in I^m_1 \times I^p_1 \) of (2.5-2) will be called **primal feasible**.

- virtually **primal feasible** (P\(^0\)-feasible) when there is an initial vector \( x(0) \) such that the LP-system is P-feasible.

- **dual feasible** (D-feasible) when system (2.5-4) possesses a solution \( u \in I^n_1 \); this solution \( u \) or a solution \( (u, v) \in I^n_1 \times I^n_1 \) of (2.5-5) will be called **dual feasible**.

- **feasible** (P- and D-feasible) when the LP-system is P- and D-feasible.

- virtually **feasible** (P\(^0\)- and D-feasible) when the LP-system is P\(^0\)- and D-feasible.

The following terms have reference to the existence of special sort of feasible solutions:

The LP-system is called:

- **primal regular** (P-regular) when (2.5-2) possesses a solution \( (x, y) \in I^m_1 \times I^p_1 \) such that \( (x/p^0) / f_0 \in I^m_1 \times \text{int}(I^p_1) \); this solution is called **primal regular**.

- **dual regular** (D-regular) when (2.5-5) possesses a solution...
The notions virtually primal regular (P⁰-regualr), regular and virtually regular may be introduced in a similar manner as the corresponding notions with respect to the feasibility.

We further shall call the LP-system (virtually) superregular if simultaneously:
- \( p \in \mathcal{K} \),
- the LP-system is (virtually) regular,
- the systems

\[
\begin{align*}
3x(t+1) - Ax(t) + y(t+1) &= \left(\frac{1}{\alpha}\right)^{a} f(t), \quad \text{for } \alpha > 0, \\
3'v(t) - A'v(t+1) - y(t) &= \left(\frac{1}{\alpha}\right)^{a} p(t), \quad \text{for } \alpha > 0,
\end{align*}
\]

have solutions \((x,y)\) and \((u,v)\) for some \(K>0\), such that \((x,y)\) is a solution of \((1.3.2)\) and \((u,v)\) is a solution of \((1.3.3)\).

The systems (2.5.1) and (2.5.2) will be called primal feasibility conditions and the systems (2.5.4) and (2.5.5) dual feasibility conditions.

The linear functionals (2.5.3) and (2.5.7) will be indicated by the terms primal and dual objective functions resp.

On the set of primal and dual feasible solutions we wish to install a partial ordering which refers directly to the optimization aspect of the LP-systems as mentioned in §1.2 and §1.6.

To this end a P-feasible solution \(x\) is called inferior with respect to a \(P\)-feasible solution \(x\), if a number \(\varepsilon > 0\) and a period \(T\) exist such that

\[
\langle p, x \rangle_T - \varepsilon < \langle p, x \rangle_T - \varepsilon, \quad T \geq 5.
\]
A 0-feasible solution \( v \) is called inferior with respect to a D-feasible solution \( \bar{v} \), if a number \( c \) and a period \( T \) exist such that
\[
< q^0, u \bar{v} > + cT < q^0, u > \geq \tau^2, \quad T \geq 2.
\] (2.5.10)

2.6 Formulation of the problem

Briefly summarized this investigation deals with the following problems:

a) When is the LP-system feasible?

b) Are the sets of P- and D-feasible solutions bounded in some respect?

c) Does an upper bound exist for the primal partial objective function and a lower bound for the dual partial objective function?

d) When do P-feasible \( \bar{x} \) and D-feasible \( \bar{u} \) exist, such that the sequences \( \{< p_n, x_n > \} \) and \( \{< p_n, u_n > \} \) converge and such that every P-feasible \( \bar{x} \) and every D-feasible \( \bar{u} \), for which the sequences \( \{< p_n, x_n > \} \) and \( \{< p_n, u_n > \} \) are not convergent, is inferior with respect to \( \bar{x}, \bar{u} \) respectively.

It appears that P- and D-feasible solutions \( \bar{x}, \bar{u} \) as mentioned under d) exists, when the LP-system is regular and \( \Delta M \leq 1 \).

With regard to the optimization aspect of the LP-system, we can conclude that these feasible solution \( \bar{x}, \bar{u} \) are "better" than those for which the sequences of partial objective functions do not converge. For this reason we further restrict ourselves to the subset of P- and D-feasible solutions, for which the sequence of partial objective functions converge, and direct the investigation to the following problems:

e) When does a P-feasible \( \bar{x} \) exists, for which the linear functional \( < p_n, x > \) on this subset of P-feasible solutions attains his supremum? Every P-feasible solution \( \bar{x} \) with this property will be called a P-optimal solution.

f) When does a D-feasible \( \bar{u} \) exists, for which the linear functional \( < q^0, u > \) on the subset of D-feasible solutions as described
above, attains his infimum? Every D-feasible solution \( \hat{G} \) with this property will be called a \( D \)-optimal solution.

\[ g \) What is the asymptotic behavior of the components \( R(t) \) and \( \hat{G}(t) \) of \( P \)- and \( D \)-optimal solutions \( R \) and \( \hat{G} \) for \( t \to \infty \)?

We write the problems posed in \( e \) and \( f \) as follows

\[
\begin{align*}
\sup_{x \in X} \langle p_x, x \rangle_m & \quad \text{s.t.} & \quad Bx(1) & \leq 0^0(1) \\
& & & & \text{subject to} \quad Bx(t+1)-Ax(t) \leq 0^1, t = 1, \ldots, T_0
\end{align*}
\]

(2.6.1)

\[
\begin{align*}
\inf_{u \in U} \langle f_u^0, u \rangle_m & \quad \text{s.t.} & \quad B' u(t+1)-A' u(t+1) & \leq 0^T, t = 1, \ldots, T_0
\end{align*}
\]

(2.6.2)

The problems (2.6.1) and (2.6.2) will be called the primal and dual problem resp. and the whole, consisting of (2.6.1) and (2.6.2) the linear programming problem (LP-problem).

We dominate the functionals \( \langle p_x, x \rangle_m \) and \( \langle f_u^0, u \rangle_m \) as the primal and dual objective function respectively.

\[ 2.7 \) Duality.

We illustrate the duality relation between the primal and dual problem already suggested with the help of a LP-problem formulated for a finite horizon problem.

To this end, we consider the following programming problem in a finite dimensional euclidean space:

\[
\begin{align*}
\max \sum_{t=1}^{T} \langle \pi(t), x(t) \rangle & \quad \text{s.t.} & \quad Bx(1) & \leq 0^0(1) \\
& & & \quad Bx(t+1)-Ax(t) & \leq 0^1, t = 1, 2, \ldots, T-1 \\
& & & & \quad -Ax(t) & \leq 0^T, t = 1, 2, \ldots, T \end{align*}
\]

(2.7.1)
where all quantities are the same as used in §2.5.
This problem can be taken as being generated by the cutting down of the primal problem (2.6.1) at a period $\tau$.

Applying the well known duality rules from the theory of linear programming in a finite dimensional space on (2.7.1) we encounter the following problem:

\[
\min \sum_{t=1}^{T+1} \phi^*(t) u(t) \quad \text{subject to } \begin{cases} 
B' u(t) - A' u(t+1) \geq \pi^p(t), \quad t=1,2,\ldots,T+1 \\
u(t) \geq 0, \quad r=1,2,\ldots,T+1.
\end{cases}
\]

(2.7.2)

This problem, too, may be considered as being generated by the cutting down of the dual problem (2.6.2).

The mathematical coherence between the primal and dual problem of §2.6 will appear to be of the same nature as that between the problems sketched above.

In this context, we remark that the dual system can be written in a similar form as the primal system:

\[
\begin{align*}
A' u(t+1) - B' u(t) & \geq \pi^p(t) \\
u(t) & \geq 0
\end{align*}
\]

\[
\text{subject to } \begin{cases} 
\phi^*(t) u(t) \geq \lambda^* T \geq 1 \\
- \phi^*(t) u(t) \geq \lambda^* T \geq 1.
\end{cases}
\]

(2.7.3)

Consequently the dual problem can be written:

\[
\sup_{u \in \mathbb{R}^n} \left\{ \frac{\phi^*(u)}{u} \right\} \quad \text{subject to } \begin{cases} 
A' u(t+1) - B' u(t) & \geq \pi^p(t), \quad t \geq 1. 
\end{cases}
\]

(2.7.4)

By virtue of this similarity between the primal and dual system (problem), further to be indicated by the term symmetry, many properties of the primal system (problem) may simply be transformed
to the dual system (problem).

Finally, we point out a difference which is caused by the appearance of the initial vector \(x(0)\) in the primal system (problem). This difference has led to the introduction of two concepts of feasibility for the primal system, whereas one type of feasibility suffices for the dual system.

### 2.8 \(\alpha\)-transformed primal and dual systems.

The \(\alpha\)-transformation \((\S 2.3)\) of \(\mathbb{R}^k\) onto itself suggests a similar transformation for the primal and dual systems, which we now introduce.

We shall call the system

\[
\begin{align*}
B\mathbf{x}(t) &+ \mathfrak{c} \mathfrak{f}^0(t) \\
B\mathbf{x}(t+1) - \alpha \mathbf{x}(t) &\in (\mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t)) \\
\mathbf{t}^* &\in \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t), \mathfrak{c} \mathfrak{e}^0(t), \mathfrak{c} \mathfrak{e}^0(t) \\
\mathbf{t}^* &\in \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t), \mathfrak{c} \mathfrak{e}^0(t) \\
\mathbf{t}^* &\in \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t), \mathfrak{c} \mathfrak{e}^0(t) \\
\mathbf{t}^* &\in \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t+1), \mathfrak{c} \mathfrak{e}^0(t), \mathfrak{c} \mathfrak{e}^0(t)
\end{align*}
\]

(2.8.1)

The \(\alpha\)-transformed primal system, and

\[
\begin{align*}
\mathfrak{A}^0\mathbf{u}(t) - \frac{1}{\alpha} \mathfrak{A}^0\mathbf{u}(t+1) &\in (\mathfrak{c} \mathfrak{w}^0(t), \mathfrak{c} \mathfrak{w}^0(t)) \\
\mathbf{u}(t+1) &\in (\mathfrak{c} \mathfrak{w}^0(t), \mathfrak{c} \mathfrak{w}^0(t)) \\
\mathbf{u}(t) &\in (\mathfrak{c} \mathfrak{w}^0(t), \mathfrak{c} \mathfrak{w}^0(t)) \\
\mathbf{u}(t) &\in (\mathfrak{c} \mathfrak{w}^0(t), \mathfrak{c} \mathfrak{w}^0(t)) \\
\mathbf{u}(t) &\in (\mathfrak{c} \mathfrak{w}^0(t), \mathfrak{c} \mathfrak{w}^0(t))
\end{align*}
\]

(2.8.2)

the \(\alpha\)-transformed dual system.

Clearly, \(\mathbf{x}\) is a \(\mathfrak{F}\)-feasible solution (of the untransformed \(\mathfrak{L}\)-system) if and only if \(\mathbf{v}_\mathfrak{F}\) satisfies (2.8.1), and \(\mathbf{u}\) is a \(\mathfrak{D}\)-feasible solution (of the untransformed \(\mathfrak{L}\)-system) if and only if \(\mathbf{v}_\mathfrak{D}\) satisfies (2.8.2).

In the same manner, we shall call
\[
\begin{align*}
\sup_{x \in \mathbb{R}^n} \langle p(x) \delta \theta, x \rangle & \leq (\alpha \rho) \delta \theta \quad (2.8.3) \\
B(x(t)) - \alpha A(x(t)) & \leq (\alpha \rho) t^{\frac{1}{r}} e^\theta(t), \quad t \geq 1.
\end{align*}
\]

The \textit{\alpha\textsuperscript{2}-transformed primal problem}, and

\[
\inf_{u \in \mathbb{R}^m} \{ f(u) \delta \theta, u \rangle \mid B'(u(t)) - \alpha A'(u(t+1)) \geq (\alpha \rho) \delta \theta p(t), \quad t \geq 1 \}.
\]

the \textit{\alpha\textsuperscript{2}-transformed dual problem}.

A specific property of these problems is:

\(x\) is a \(\alpha\textsuperscript{2}\)-optimal solution of the untransformed LP problem if and only if \(x\) is a \(\alpha\textsuperscript{2}\)-optimal solution of the \(\alpha\textsuperscript{2}\)-transformed primal problem. A similar relation holds for the dual problem.

3.9 Concepts with respect to the structure of the LP system.

We shall analyse the LP system under different suppositions.

The most important of which are the following:

The LP system is called:

- \textit{exponential}, when

\[
\begin{align*}
& f(t) = e^t \\
& p(t) = e^t
\end{align*}
\]

\(t \geq 1\),

- \textit{semi-exponential}, when

\[
\begin{align*}
& f(t) = e^t \\
& p(t) = e^t
\end{align*}
\]

\(t \geq 1\), for some \(T \geq 1\),

\text{i.e. if a period \(T \geq 1\) exists such that the sequences \(\{f(t)\}_{t=1}^{\infty}\) and \(\{p(t)\}_{t=1}^{\infty}\) are constant,

- \textit{primal directed (P-directed)}, if every row vector \(b_i\), of \(B\),

which possesses a negative component, corresponds with a non-

negative row vector \( s_j \) of \( A \), and with non-negative components \( f_j(t) \). \( t \geq 0 \) if the sequence \( \{ f(t) \} \). (see also §1.)

- **dual directed** (D-directed), if every column \( s_j \) of \( A \), which possesses a negative component, corresponds with a non-negative column vector \( b \) of \( B \), and with non-positive elements \( p_j(t) \). \( t \leq 0 \) of the sequence \( \{ p(t) \} \).

We remark that the latter two definitions are symmetric; for writing the dual feasibility conditions as follows

\[
A'w(t+1) - B'u(t) \leq \mathbb{E}(p(t)),
\]

it appears that they correspond completely.

Finally, with the help of two examples, we introduce a brief notation for suppositions about the LP-system/problems:

- **LP-system** (\( P^- \) or D-directed; \( p(t) \rightarrow p \), \( t \rightarrow \infty \)): the system is supposed to be \( P^- \) or D-directed and the sequence \( \{ p(t) \} \) to converge to \( p \in \mathbb{R}^n \).

- **LP-problem** (\( f^0, p \) \( \in \mathbb{R}^n \times \mathbb{R}^m \); \( P^- \) or D-directed): \( f^0 \) and \( P \) are supposed to be vectors of \( \mathbb{R}^n \), \( P \), resp. and such that, for these \( f^0 \) and \( p \), the LP-problem is \( P^- \) or D-directed.
3. DIRECTEDNESS, FEASIBILITY, AND REGULARITY.

2.1 Introduction.

In this chapter a number of conditions will be derived with respect to the feasibility, regularity and boundedness of feasible solutions. In these derivations the concept of directedness takes a central place.

2.2 Theorem.

The L.P.-system is then and only then P-directed if for every \( f(t), t \geq 1 \):

each \( (x,y,z) \in \mathbb{R}^{n+n+1} \) satisfying
\[
Bx - Ay - z \leq f(t),
\]
also satisfies
\[
-Ay + z \leq f(t).
\]

Proof.

Necessary: suppose that for some \( t \geq 1 \), there is a \( (x,y,z) \in \mathbb{R}^{n+n+1} \) such that
\[
Bx - Ay - z \leq f(t), \quad -Ay + z \not\leq f(t).
\]

Then an index \( i \) exists for which \( b_{ij} \neq 0 \) and for which \( a_{ij} \neq 0 \) or \( f_j(t) < 0 \). This, however, is impossible in connection with the definition of P-directedness.

Sufficient: assume that the L.P.-system is not P-directed, then there is a \( b_{ij} < 0 \) such that \( a_{ij} \neq 0 \) or \( f_j(t) < 0 \) for some \( t \geq 1 \). This implies that there exists a \( (x,y) \in \mathbb{R}^n \) such that for some \( t \geq 1 \) and row-index \( i \):
\[
\begin{align*}
\begin{cases}
    b_1, x^t - a_1, y & \leq f_1(t) \\
    -a_1, y & > f_2(t)
\end{cases}.
\end{align*}
\] (3.2.3)

From this it appears that it is possible to choose a \( z \in \mathbb{H}^n \):
\[ x_1 = 0 \] and sufficiently large the other components, such that \((x,y,z)\) satisfies (3.2.1) but not (3.2.2).

### 3.3 Theorem

The LP-system is then and only then D-directed if for every \( p(t), t \geq 0 \):

- each \((u,v,\omega) \in \mathbb{R}^{m \times n}\) satisfying
  \[
  b^t u - A^t v + \omega \geq p(t),
  \] (3.3.1)

also satisfies
  \[
  b^t u + \omega \geq p(t).\] (3.3.2)

**Proof.**

The theorem follows from theorem 3.2 and from the symmetry between the primal and dual system.

### 3.4 Remark

The following two propositions only will be used as auxiliary theorems.

### 3.5 Proposition

Let \( A \) be a diagonal \( n \times n \)-matrix which is defined for a LP-system
(P- or D-directed) as follows:

- in case the LP-system is P-directed:
  \[ A \equiv I, \]

- in case the LP-system is not P-directed:
\[\lambda_{ij} = 1, \text{ if } a_{ij} \neq 0\]
\[\lambda_{ij} = 0, \text{ if } a_{ij} = 0\]
then for every \((x, y, z) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) satisfying
\[Bx(t) - \lambda x(t-1) + \gamma y(t) = \gamma^2 f(t) z(t), \quad t \geq K,\]
(3.5.1)

for some \(\gamma > 0\), \(K \geq 1\), and for every monotonous non-increasing sequence of numbers \(\{p(t)\}_{K-1}^\infty\), there exists a
\((\{x(t)\}_{K-1}^\infty, \{y(t)\}_{K}^\infty) \in \mathbb{R}^n \times \mathbb{R}^m\) with \(x(K-1) = 0(K-1) x(K-1)\) such that
\[Bx(t) - \lambda x(t-1) + y(t) = p(t-1) (\gamma^2 f(t) z(t))\]
(3.5.2)
\[y(t) = p(t) \lambda x(t) + p(t-1) (1-\lambda) x(t-1), \quad t \geq K\]
\[x(t) = \theta(t) y(t)\]

Proof:

First consider the case that the LP-system is P-directed, so that \(\lambda = 1\).
From theorem 3.3 it then follows that every \((x, y, z) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\)
satisfying (3.5.1) for some \(\gamma > 0\), \(K \geq 1\), also satisfies
\[-Ax(t-1) \leq \gamma^2 f(t) z(t), \quad t \geq K.\]

Since the sequence \(\{p(t)\}_{K-1}^\infty\) is monotonous non-increasing, this implies that
\[-(p(t-1) - p(t)) \lambda x(t-1) \leq (p(t-1) - p(t)) (\gamma^2 f(t) z(t)), \quad t \geq K.\]
(3.5.5)
The equalities (3.5.1) imply:
\[p(t) (Bx(t) - \lambda x(t-1) + y(t)) = p(t) (\gamma^2 f(t) z(t)), \quad t \geq K.\]
(3.5.6)
By adding (3.5.5) and (3.5.6) we find
\[ B\Theta(t)x(t)+A\Theta(t-1)x(t-1)+\Theta(t)y(t)\leq \Theta(t-1)(y^f(t)+z(t)), t \geq K. \]

Since \( A = I \) we may conclude that there exists a \((x,y) \in \mathbb{R}^n \times \mathbb{R}^m\)

satisfying (3.5.2).

Now we consider the case that the LP-system is not P-directed.

Then the D-directedness and the definition of \( \Lambda \) imply that
\[
\begin{align*}
B\Lambda & \geq 0, \\
A(1-\Lambda) & \geq 0.
\end{align*}
\]

Since \([\Theta(t)]_{K-1}^m\) is monotonous non-increasing and \([x(t)]_{K-1}^m\) is non-negative, we may conclude that
\[
\begin{align*}
B\Lambda (\Theta(t)-\Theta(t-1))x(t) & \leq 0, \\
-A(1-\Lambda)(\Theta(t-1)-\Theta(t))x(t) & \leq 0.
\end{align*}
\]

The equality (3.5.1) implies
\[
\Theta(t-1)(Bx(t)+Ax(t-1)+y(t))=\Theta(t-1)(y^f(t)+z(t)), t \geq K.
\]

Adding (3.5.8) and (3.5.9) it appears that there exists a
\((\tilde{x}(t))_{K-1}^m, (\tilde{y}(t))_{K}^m\) satisfying (3.5.2).

3.6 Proposition.

If the LP-system is P- or D-directed, then for every
\((x,y) \in \mathbb{R}^n \times \mathbb{R}^m\)

satisfying
\[
Bx(t)+Ax(t-1)+y(t) = y^f(t), t \geq K.
\]

for some \( y > 0, K \geq 1 \), and for every \( a > 0, T > K \), a
\((\tilde{x},\tilde{y}) \in \mathbb{R}^n \times \mathbb{R}^m\) exists such that
\[
\begin{align*}
(U - \lambda I)x &\in \n + \sum_{t=K}^{T} \frac{(\gamma/\alpha)^t}{t!} f(t) x + \frac{1}{\alpha} Ax (K-1) \\
\gamma &\geq \sum_{t=K}^{T-1} \frac{(\gamma/\alpha)^t}{t!} x(t) \\
\gamma &\geq 0
\end{align*}
\]

Proof.

Let \((\alpha, \gamma) \in \mathbb{R}^n \times \mathbb{R}\) be a solution of \((3.6.1)\) for some \(\gamma > 0\), \(K > 1\). Defining the sequence \(\{(\theta(t))_K^{\infty}\}\) for some \(T > K\) by

\[
\begin{align*}
\theta(t) &:= 1, \quad t = K, K+1, \ldots, T-1 \\
\theta(t) &:= 0, \quad t \geq T
\end{align*}
\]

it follows from proposition 3.5 that \(\{(x(t))_K^{\infty}, (\chi(t))_K^{\infty}\}\) exists such that

\[
\begin{align*}
Bx(K) &\geq \gamma K f(K) + \frac{1}{\alpha} Ax (K-1) \\
Bx(t+1) - Ax(t) &\geq \gamma t f(t+1), \quad t = K, K+1, \ldots, T-1 \\
-\lambda x(T) &\leq 0
\end{align*}
\]

\[
\begin{align*}
x(t) &\geq x(t), \quad t = K, K+1, \ldots, T-1 \\
\chi(t) &\geq \gamma (t), \quad t = K, K+1, \ldots, T-1 \\
\chi(T), \chi(T) &\geq 0
\end{align*}
\]

From \((3.6.1)\) the following inequalities may be derived
\[
\begin{align*}
(B - \frac{1}{2}A) \sum_{t=1}^{T} \left( \frac{1}{2} \right) y(t) + \sum_{t=K}^{T} \frac{1}{2} x(t) & \leq \sum_{t=K}^{T} \left( \frac{1}{2} \right) f(t) + \frac{1}{2} \lambda x(K - 1) \\
\sum_{t=K}^{T} \left( \frac{1}{2} \right) x(t) & \geq \sum_{t=K}^{T-1} \left( \frac{1}{2} \right) x(t) \\
\sum_{t=1}^{T} \left( \frac{1}{2} \right) y(t) & \geq \sum_{t=1}^{T-1} \left( \frac{1}{2} \right) y(t)
\end{align*}
\]  \hspace{1cm} (3.6.4)

From this the proposition follows immediately.

3.7 Remark.

The manner in which the supposition that the LP-system is \( P \)- or \( D \)-directed functions appears especially from proposition 3.6.

By this it is possible to cut down the LP-system to a system with a finite number of periods, which leads to a finite number of linear inequalities, as constructed in (3.6.2). The latter is essential to the argumentation of the next theorem.

3.8 Theorem.

For a LP-system \( (P \text{- or } D \text{-directed}; f(t) \rightarrow 2, t \rightarrow -) \) the following properties hold:

a) If the LP-system is \( P^0 \)-feasible, then the system

\[
\begin{align*}
(B - \frac{1}{2}A)z & \leq 2 \\
z & \geq 0
\end{align*}
\]  \hspace{1cm} (3.8.1)

has a solution.

b) If for some initial vector the LP-system has a \( P \)-feasible solution \( (x, y) \) such that \( y(t) \geq \delta t y \) for some \( y \in \text{int} (R^m) \) then the system

\[
\begin{align*}
(B - \frac{1}{2}A)z & < 2 \\
z & \geq 0
\end{align*}
\]  \hspace{1cm} (3.8.2)
has a solution.

(c) If for some \( n \geq 1 \) and \( \tilde{y} \in \text{int}(\mathbb{R}_+^n) \) the system

\[
\begin{align*}
8x(t) - Ax(t-1) + y(t) &= \left( \frac{1}{2} \right)^t f(t) \\
x(t-1) &\geq 0 \\
y(t) &= \left( \frac{1}{2^n} \right)^{\frac{1}{n}}
\end{align*}
\]

has a solution, then the system

\[
(B-Y)z \leq \tilde{y},
\]

has a solution.

\[\quad (3.8.3)\]

Proof.

(a) Let \((x,y) \in 1^{\mathbb{N}}\mathbb{N}^\ast\) be a \( P \)-feasible solution for some \( x(0) \). Then it follows from proposition 3.6 that the system

\[
\begin{align*}
(B - \frac{1}{P})x + \tilde{y} &= \frac{1}{T} \sum_{i=1}^T f(t) \\
\tilde{x} &= \sum_{i=1}^T \left( \frac{1}{P} \right)^{\frac{i}{n}} x(t) \\
\tilde{y} &= \sum_{i=1}^T \left( \frac{1}{P} \right)^{\frac{i}{n}} y(t)
\end{align*}
\]

has a solution for every \( T > 1 \).

Defining

\[
C := (x = (B - \frac{1}{P})x + \tilde{y} | x \geq 0, \ \tilde{y} \geq 0),
\]

\[
g(T) := \frac{1}{T} \sum_{i=1}^T f(t), \quad T > 1,
\]

system (3.8.4) implies that
\text{\textit{g}(t) \in C, \quad \text{T} > 1.} \quad (3.8.7)

The supposition \text{\textit{f}(t) \to \hat{f}}, \quad t = \infty \text{ implies}
\text{\textit{g}(t) \to \hat{g}}, \quad t = \infty. \quad (3.8.8)

From the definition of C it follows (1.74) that this set is closed. On this ground, (3.8.7) and (3.8.8) imply \hat{f} \in C.
In connection with the definition (3.8.5) of C we may conclude that the system (3.8.1) has a solution.

(b) Let \((x,y) \in \mathbb{R}^{n+m}\) be a \(P\)-feasible solution for some \(x(0)\) such that
\[ y(t) \preceq \sigma^T \hat{y}, \quad t \geq 1, \quad (3.8.9) \]
for some \(\hat{y} \in \text{int}(\mathbb{R}^n_{+})\). From (3.8.4), (3.8.5), (3.8.6) and (3.8.9) it may be derived that
\[ (g(T) - \lambda \hat{y}) \in C, \quad T > 1. \]

Then the convergence (3.8.8) implies \((\hat{y} - \lambda \hat{y}) \in C\) and there by the existence of a solution for (3.8.2).

(c) From proposition 3.6 it may be derived that the system
\[
\begin{align*}
(\tilde{\mathbf{A}} - \mathbf{A})^T \mathbf{y} + \mathbf{y} &= \frac{1}{T} \left( \frac{\mathbf{f}(t)}{T + K \mathbf{f}(t)} \right) \\
\mathbf{z} \geq 0 \\
\mathbf{z} &\geq 1 \hat{y}
\end{align*}
\]
has a solution for every \(T > K\). The proof may be derived in a similar way as the one for (b).
3.9 Theorem.

For a LP-system \((P^- \text{ or } D^-\text{-directed; } p(t) \rightarrow \bar{p}, t \rightarrow \infty)\) the following properties hold:

a) If the LP-system is D-feasible, then the system

\[
(B^-\bar{N}A')u > \bar{p} \]
\[
u \geq 0
\]

has a solution.

b) If the LP-system has a D-feasible solution \((u, \nu)\) such that

\[
u(t) > t^\top \bar{v}, t \geq t_0 \text{ for some } \bar{v} \in \text{int}(R_+^n),
\]

then the system

\[
(B^-\bar{N}A')u > \bar{p} \]
\[
u \geq 0
\]

has a solution.

c) If for some \(K_+^n\) and \(\bar{v} \in \text{int}(R_+^n),\) the system

\[
B^-u(t)-A^-u(t-1)-v(t) = (\begin{array}{c} -1 \\ \bar{l} \end{array})^\top p(t)
\]
\[
u(t) > 0, t \geq K,
\]
\[
u(t) > (\begin{array}{c} -1 \\ \bar{l} \end{array})^\top \bar{v}
\]

has a solution, then the system

\[
(B^-\bar{N}A')u > \bar{p} \]
\[
u \geq 0
\]

has a solution.
Proof.

The theorem follows from theorem 3.8 and from the symmetry between the primal and the dual system.

3.10 Remark.

For a LP-system (P or D-directed; f(t) → 2; t → 2; p(t) → p; c → 0) the theorems 3.8 and 3.9 may be resumed as follows:

a) If the LP-system is p°-feasible then the system

\[(B-1\over p)z \leq \bar{y}\]
\[z \geq 0\]  \hspace{1cm} (3.10.1)

has a solution.

b) If the LP-system is D-feasible then the system

\[(B' - nA)u > \bar{p}\]
\[u \geq 0\]  \hspace{1cm} (3.10.2)

has a solution.

c) If the LP-system is P°-regular, then the system

\[(B-1\over p)z < \bar{y}\]
\[z \geq 0\]  \hspace{1cm} (3.10.3)

has a solution.

d) If the LP-system is D-regular then the system

\[(B' - nA)u \geq \bar{y}\]
\[u \geq 0\]  \hspace{1cm} (3.10.4)
has a solution.

a) If the LP-system is virtually superregular, then the systems

\[
\begin{align*}
(B-\gamma A)z &< \gamma \tilde{f} \\
z &\geq 0,
\end{align*}
\]  

(3.10.3)

\[
\begin{align*}
(B' - \frac{1}{2} A')w &> \frac{\gamma}{p} \\
w &\geq 0,
\end{align*}
\]  

(3.10.6)

have a solution.

From the next two theorems one may derive a relation between (3.10.3) and (3.10.5) and between (3.10.4) and (3.10.6).

3.11 Theorem.

If the system

\[
\begin{align*}
(B-\gamma A)z &\leq \gamma \tilde{f} - h \\
z &\geq 0,
\end{align*}
\]  

(3.11.1)

belonging to a LP-system (P- or D-directed; \( f(t) \rightarrow \tilde{f}, t = \infty \)), has a solution for some \( \gamma > 0 \) and \( h \in \mathbb{R}_+^m \), then the system

\[
\begin{align*}
(B-\delta A)z &\leq \delta \tilde{f} - h \\
z &\geq 0
\end{align*}
\]  

(3.11.2)

has a solution for every \( \delta \geq \gamma \).

Proof.

First consider the case that the LP-system is P-directed. If \( z \) satisfies (3.11.1) for some \( \gamma > 0 \), \( h \in \mathbb{R}_+^m \), then \( z \) also...
satisfies

\[-\gamma z \leq \gamma.\]

This implies that for every \(\alpha \geq \gamma\) the following inequality holds:

\[-(\alpha-\gamma)z \leq \left(\frac{\alpha}{\gamma} - 1\right)\gamma.\]  \hfill (3.11.3)

Addition of (3.11.1) and (3.11.3) gives

\[(B-\alpha A)z \leq \left(\frac{\alpha}{\gamma}\right)\gamma - h.\]

Hence it appears that (3.11.2) has a solution.

For the case that the LP-system is not \(P\)-directed we define the diagonal \(n \times n\)-matrix \(\lambda\) in the following manner

\[\lambda_{jj} = 1, \text{ if } a_{jj} \neq 0,\]

\[\lambda_{jj} = 0, \text{ if } a_{jj} = 0.\]

The \(D\)-directedness of the LP-system then implies

\[
\begin{align*}
\lambda A z & \geq 0 \\
(\lambda(I-A)) z & \geq 0
\end{align*}
\] \hfill (3.11.4)

If \(z \in \mathbb{R}^n\) satisfies (3.11.1) for some \(\gamma > 0, h \in \mathbb{R}^n\), then (3.11.1) and (3.11.4) imply for every \(\alpha \geq \gamma\):

\[
\begin{align*}
\frac{\gamma}{\lambda} z + (I-A)z & \leq \gamma\alpha + \lambda(I-A)z \\
& \leq \gamma - h.
\end{align*}
\]

Defining \(\tilde{z} = \gamma z + (I-A)z\), it appears that

\[
(\tilde{B} - \alpha A)\tilde{z} \leq \tilde{y} - h.
\]

Hence we conclude that (3.11.2) has a solution for every \(\alpha \geq \gamma\).
3.12 Theorem.

if the system

\[ (R' - \gamma A')w \leq \bar{p} + q \]
\[ w \geq 0 \] \hspace{1cm} \text{(3.12.1)}

belonging to a LP-system (P- or D-directed; \( p(t) = \bar{p}, t = m \))
has a solution for some \( \gamma > 0 \) and \( q \in \mathbb{R}^n \), then the system

\[ (R' - \alpha A')w \leq \bar{p} + \frac{q + \alpha q}{1 + \alpha} \]
\[ w \geq 0 \] \hspace{1cm} \text{(3.12.2)}

has a solution for every \( \alpha \in [0, M] \).

Proof.

This theorem follows from theorem 3.11 and from the symmetry
between the primal and dual system.

3.13 Theorem.

For a LP-system \( (f(t) = \bar{f}, p(t) = \bar{p}, t \geq 1) \) the following properties
hold:

a) If the system

\[ (R - \frac{1}{\delta} A)x \leq \bar{f} \]
\[ x \geq 0 \] \hspace{1cm} \text{(3.13.1)}

has a solution then the LP-system is \( P^0 \)-feasible.

b) If the system

\[ (R - \frac{1}{\delta} A)x \leq \bar{f} \]
\[ x \geq 0 \] \hspace{1cm} \text{(3.13.2)}

has a solution then the LP-system is \( D^0 \)-feasible.
has a solution then the LP-system is F'-regular.

c) If the system
\[
\begin{align*}
(b' - n'a')w & \leq \bar{y} \\
\bar{w} & \geq 0,
\end{align*}
\]
(3.13.3)

has a solution then the LP-system is D-feasible.

d) If simultaneously the systems
\[
\begin{align*}
(b' - n'a')z & \leq \bar{y} \\
z & \geq 0,
\end{align*}
\]
(3.13.4)

\[
\begin{align*}
(b' - \frac{1}{2}a')w & \geq \bar{n} \\
w & \geq 0,
\end{align*}
\]
(3.13.5)

have a solution and the LP-system is F- or D-directed and
\(d < 1\), then the LP-system is virtually superregular.

**Proof.**
If \(z\) satisfies (3.13.1) then \(x(t) = p^t z, t \geq 1\) is a F-feasible solution.

The properties b) and c) may be proved in a similar manner.

If \(d < 1\) and if the LP-system is F- or D-directed then by virtue of theorem 3.11 and 3.12 the solvability of (3.13.4) and (3.13.5) imply the solvability of the systems (3.13.2) and (3.13.3) resp.

Further proof that the conditions of an virtually superregular arc satisfied, can be given in a similar manner as done at property a).

**3.14 Remark.**
The next theorems include some statements about the boundness of the set of feasible solutions. We restrict ourselves to the most
relevant question, namely: in which circumstances all $F$-feasible solutions are $p$-dominated and all $D$-feasible solutions $\gamma$-dominated.

3.15 Proposition.

If the $LP$-system has a $F$-feasible solution $(x,y)$ such that

\[
y(t) \leq p^\top x, \quad t \in \mathbb{N},
\]

for some $p \geq 1$ and $y \in \text{int}(\mathbb{N}^n)$, and if the linear system

\[
(\mathbb{R}^{\frac{1}{p}}A)x \leq 0 \\
x \geq 0,
\]

has a solution, then a $F$-feasible solution exists which is not $p$-dominated.

Proof.

The positivity of $x$, the homogeneity and the solvability of the system (3.15.2) imply that a $z$ exists satisfying

\[
Bz \leq x \\
(xz + \frac{1}{p}A)x \leq 0 \\
z \geq 0,
\]

Now let $(x,y)$ be a $F$-feasible solution satisfying (3.15.1), so that

\[
Bx(t) = \Delta x(t-1) \leq p^\top f(t), \quad t=1, \ldots, K,
\]

\[
Bx(t) = \Delta x(t-1) + p^\top y \leq p^\top f(t), \quad t \in \mathbb{N},
\]

then (3.15.3) and (3.15.5) imply:
\[ R(x(t)+(t-K) \delta^t z) - A(x(t-1)+(t-1-K) \delta^{t-1} z) \leq \delta^t f(t), \quad t \geq K. \]

Hence it appears that \( \{ \hat{x}(t) \}_{t=1}^{\infty} \) defined as
\[
\hat{x}(t) = \begin{cases} x(t) & t = 1, 2, \ldots, K \\ x(t) = x(t) + (t-K) \delta^t z, & t > K \end{cases}
\]
is a \( P \)-feasible solution, which is not \( p \)-dominated because of the fact that \( z > 0 \).

3.16 Proposition.

If the LP-system has a \( P \)-feasible solution such that
\[ R x(K) - A x(K-1) \leq \delta^K f(K), \quad \text{for some } K \geq 1, \quad (3.16.1) \]
and if the linear system
\[
\begin{align*}
(B - \frac{1}{\beta} A) z & \leq 0 \\
z & \geq 0
\end{align*}
\]
(3.16.2)

has a solution for some \( \beta > \sigma \), then there exists a \( P \)-feasible solution which is not \( p \)-dominated.

Proof.

If \( x \) is a \( P \)-feasible solution which satisfies (3.16.1) for some \( K \geq 1 \) and if \( z \) satisfies (3.16.2) for some \( \beta > \sigma \), it may be shown that \( \{ \hat{x}(t) \}_{t=1}^{\infty} \) defined by
\[
\hat{x}(t) = \begin{cases} x(t) & t = 1, 2, \ldots, K-1 \\ x(t) + (t-K) \delta^t z, & t > K \end{cases}
\]
is a P-feasible solution which is not p-dominated, because of the fact that \( b > 0 \) and \( z \geq 0 \).

A.1.7 Proposition.

All P-feasible solutions of a LP-system (P of 0-directed; P-feasible) are p-dominated, if the system

\[
\begin{align*}
(B - \frac{1}{b} A) \pi & \leq 0, \\
z & \geq 0
\end{align*}
\]

(3.17.1)

has no solution.

Proof.

The supposition that (3.17.1) is unsolvable, is equivalent with the supposition that the system

\[
\begin{bmatrix}
B - \frac{1}{b} A \\
-1
\end{bmatrix}z \leq 0,
\]

has no solution.

By virtue of Stiemke's theorem\(^{(3)}\), this implies that the system

\[
\begin{align*}
(g' - \frac{1}{b} A') \pi - \psi &= 0, \\
\pi, \psi &> 0
\end{align*}
\]

has a solution.

Hence there also exists an \( \delta \in 0, \delta \) (viz. close enough to 0) such that

\(^{(3)}\) Stiemke's theorem: the system of linear equalities \( Ax = 0 \), \( x \geq 0 \), has a solution if and only if the system \( A^*y = 0 \) has no solution.
\[(B' - \frac{1}{\alpha}A')u - v = 0\]
\[u, v > 0\]

has a solution.

Now let \( (x, y) \) be a \( P \)-feasible solution, then by virtue of proposition 3.6 it follows that

\[
\begin{align*}
(B' - \frac{1}{\alpha}A)x & \leq \frac{1}{\alpha}Ax(0) + \sum_{t=1}^{T+1} (\frac{1}{\alpha})^t f(t) \\
- x & \geq \sum_{t=1}^{T+1} (\frac{1}{\alpha})^t x(t)
\end{align*}
\]

has a solution for every \( T \geq 1 \). Choosing \( \alpha \in ]0, \alpha[ \) in such a way that (3.17.2) has a solution, and multiplying (3.17.3) by \( \alpha^T \), one may conclude that for every \( P \)-feasible solution \( x \) and for every \( T \geq 1 \) the system

\[
\begin{align*}
(B' - \frac{1}{\alpha}A)x & \leq \alpha^T \begin{pmatrix} (\frac{1}{\alpha})x(0) + \sum_{t=0}^{T} (\frac{1}{\alpha})^t f(T+1-t) \end{pmatrix} \\
- x & \geq x(T)
\end{align*}
\]

is solvable.

Since \( \{f(t)\}_t \in 1^m \) and \( \|z\| < 1 \), the sequence \( \sum_{t=0}^{T} (\frac{1}{\alpha})^t f(T+1-t) \) is convergent.

Consequently a vector \( g \in \mathbb{R}^m \) exists such that for every \( P \)-feasible solution \( x \) and every \( T \geq 1 \) the system

\[
\begin{align*}
(B' - \frac{1}{\alpha}A)x & \leq \alpha^T g \\
- x & \geq x(T)
\end{align*}
\]

has a solution.
If \((\bar{v}, \bar{u})\) is a solution of (3.17.2), then by multiplying (3.17.5) by \((\bar{u}, \bar{v})'\), one can derive that

\[
\begin{align*}
\bar{v}'x & \leq \bar{u}'y'g \\
\bar{v}'x & \geq \bar{v}'x(Z)
\end{align*}
\]

has a solution for every \(P\)-feasible solution \(x\) and every \(T'\). Since \(\bar{v} > 0\), this implies that every \(P\)-feasible solution is \(P\)-dominated.

3.18 Remark.

From the last two propositions it appears that for a LP-system \((P\text{-} or \ D\text{-}directed)\) the unsolvability (3.17.1) implies that (3.16.2) has no solution for every \(B > 0\). This result can also be obtained from theorem 3.11. Namely, if (3.11.1) has a solution for some \(\gamma: \bar{u}_i = \bar{u} / B\) and \(h = 0\), then (3.11.2) has a solution for \(\bar{u} = \bar{u}/B\).

The next two theorems give a summary of the latter three propositions for the primal and dual system.

3.19 Theorem.

Every \(P\)-feasible solution of a LP-system \((P\text{-} or \ D\text{-}directed; \ P\text{-}regular)\) is \(P\)-dominated if and only if the system of linear inequalities

\[
\begin{align*}
(B - \frac{1}{B}A)x & \leq 0' \\
x & \geq 0
\end{align*}
\]

(3.19.1)

has no solution.

3.20 Theorem.

Every \(D\)-feasible solution of a LP-system \((P\text{-} or \ D\text{-}directed; \ D\text{-}regular)\) is \(D\)-dominated if and only if the system of linear inequalities

\[
\begin{align*}
(B - \frac{1}{B}A)x & \leq 0' \\
x & \geq 0
\end{align*}
\]

has no solution.
\[(3^\prime = \pi \mathbf{A}^\prime) \mathbf{v} \geq 0 \]
\[\mathbf{w} \geq 0 \] (3.20.1)

has no solution.

3.2) Theorem.

For a LP-system \((F^- \text{ or } D\text{-directed}; F^- \text{ and } 0\text{-regular}; \omega \leq 1)\) the following properties hold:

a) if every \(F\)-feasible solution is \(D\)-dominated, then not all \(D\)-feasible solutions are \(F\)-dominated.

b) if every \(D\)-feasible solution is \(\pi\)-dominated, then not all \(F\)-feasible solutions are \(D\)-dominated.

Proof.

a) If all of the \(F\)-feasible solutions are \(D\)-dominated, then theorem 3.19 implies that

\[(3 = \frac{1}{\rho} \mathbf{A}) \mathbf{r} \leq 0 \]
\[\mathbf{r} \geq 0 \]

is unsolvable.

By virtue of Stiemke's theorem this implies that

\[(3^\prime = \frac{1}{\rho} \mathbf{A}^\prime) \mathbf{w} > 0 \]
\[\mathbf{w} > 0 \]

has a solution.

Since \(\frac{1}{\rho} > \pi\), theorem 3.12 implies that the system

\[(3^\prime = \pi \mathbf{A}^\prime) \mathbf{v} \geq 0 \]
\[\mathbf{w} \geq 0 \]
is solvable.
By virtue of theorem 3.20, one can conclude that not all D-feasible solutions are \( \tau \)-dominated.

b) This property follows from the symmetry between the primal and from the dual system and property a).
4. PARTIAL OBJECTIVE FUNCTIONS.

4.1 Introduction.

In this chapter, the feasibility of the primal system is related to certain properties of the dual partial objective functions and, the other way round, the feasibility of the dual system is related to certain properties of the primal partial objective functions. Previously, we introduced the concept of consistence:

- the primal system is called consistent, or the LP-system is called P-consistent, if there is a P-feasible solution $x$, for which the partial objective functions $\langle P, x \rangle_T$, $T \geq 1$ have a lower bound. Consequently, a P-feasible solution which possesses this property is called a P-consistent solution.

- the dual system is called consistent, or the LP-system is called D-consistent, if there is a D-feasible solution $u$, for which the partial objective functions $\langle D, u \rangle_T$, $T \geq 1$ have an upper bound. A D-feasible solution with this property is called a D-consistent solution.

These denominations are chosen because only in a LP-system which is P-consistent, it is sensible to search for a P-optimal solution. A similar statement can be given with respect to D-optimal solutions.

In the following expressions like
\[ \sum_{t \in K} a(t) b(x(t)), \text{ where } a, b \in \mathbb{R}^K \]
and
\[ \sum_{t \in L} a(t) b(x(t)), \text{ where } a, b \in \mathbb{R}^L \]
will be denoted by $\langle a, b \rangle_{x, L}$.

A feasible solution of a LP-system will be denoted by $(\langle x, y \rangle, \langle u, v \rangle)$, where $(x, y)$ is the P-feasible solution and $(u, v)$ the D-feasible solution.

4.2 Proposition.

For every feasible solution $(\langle x, y \rangle, \langle u, v \rangle)$ of a LP-system the following equalities hold:
\[ <P,v>_K,L = <\xi_u,u>_K,L + u(K)'Ax(K-1) = <u,y>_K,L \]
\[ - <v,x>_K,L = u(L+1)'Ax(L), \forall K \geq l \]

Proof.

If \((x,y),(u,v))\) is a feasible solution, then for every pair of periods \(L,K\): \(L \geq K \geq l\):

\[ <P,v>_K,L = \sum_{t=K}^{L} \left( (x'(u(t)-A'u(t+1)-v(t))'x(t) - \right. \]
\[ - \sum_{t=K}^{L} (u(t)'(Bx(t)-Ax(t)+v(t))'x(t)) + \]
\[ + u(K)'Ax(K-1)-u(L+1)'Ax(L) = \]
\[ = <\xi_u,u>_K,L - <u,y>_K,L - <v,x>_K,L + u(K)'Ax(K-1) - \]
\[ = -u(L+1)'Ax(L). \]

After regrouping the equalities (4.2.1) follow.

4.3 Proposition.

For every feasible solution \((x,y),(u,v))\) of a LP-system (F-directed) the following inequalities hold.

\[ <P,v>_K,L \leq <\xi_u,u>_K,L - (A'Ax(K-1)-u,y>_K,L - <v,x>_K,L, \]
\[ \forall K \geq l. \quad (4.3.1) \]

Proof.

Since the LP-system is F-directed, every F-feasible solution \((x,y)\) satisfies:

\[ -Ax(t) \leq \delta^{t+1} f(t+1), \quad t \geq 0 \quad (4.3.2) \]

Since \(u \in \mathbb{L}^Z\), the inequalities (4.3.1) follow from (4.2.1) and (4.3.2).
4.4 Proposition.
For every feasible solution \((x,y),(u,v))\) of a LP-system (D-directed) the following inequalities hold:

\[
<f_{u}^T (x,y) - <f_{v}^T (u,v)\rangle_{E_L K} - <u,v>_{E_L K}\rangle_{L},<u,v>_{E_L K}\rangle_{L} > 0. \\
(4.4.1)
\]

Proof.
The D-directedness implies that every D-feasible solution \((u,v)\) satisfies

\[
A'(u(t) - v(t)) > 0, \quad t \geq 0. \\
(4.4.2)
\]

Since \((x,y) \in D^0 + 1^\infty\) one can derive the inequalities (4.4.1) from (4.4.1) and (4.4.2).

4.5 Theorem.
For every feasible solution \((x),(u))\) of the LP-system the following properties hold:

a) If the LP-system is P-directed then

\[
<f_{u}^T (x) > 0, \quad T^0 > 0. \\
(4.5.1)
\]

b) If the LP-system is D-directed then

\[
<f_{u}^T (x) > 0, \quad T^0 > 0. \\
(4.5.2)
\]

c) If the LP-system is P- or D-directed and \(<f_{u}^T > 0\) and \(<f_{u}^0 > 0\) exist, then

\[
<f_{u}^T (x) > 0, \quad <f_{u}^0 > 0.
\]

Proof.
The theorem follows from 4.3, 4.4 and from the non-negativity of feasible solutions.
4.6 Corollary.

The primal partial objective functions of a LP-system (P-or D-directed; P-feasible; D-consistent) are bounded above.

The dual partial objective functions of a LP-system (P-or D-directed; P'-consistent; D-feasible) are bounded below.

4.7 Theorem.

If a LP-system (P-or D-directed) possesses a regular solution which is consistent, then $\rho \leq 1$.

Proof.

The regularity of a LP-system implies that a regular solution $((x,y),(u,v))$ exists, such that there are vectors $x, y \in \text{Int}(\mathcal{K}_p)$, $u, v \in \text{Int}(\mathcal{K}_d)$, for which

$$
\begin{align*}
(x(t), y(t)) & \geq e^t (x, y) \\
(u(t), v(t)) & \geq e^t (u, v)
\end{align*} \quad t \geq 1
$$

(4.7.1)

Now suppose that this regular solution $((x,y),(u,v))$ is consistent as well; i.e., a lower bound $M_p$ exists for the primal partial objective functions and an upper bound $M_d$ for the dual partial objective functions. For these numbers $M_p$ and $M_d$ we have:

$$
\begin{align*}
\langle p, x \rangle & \geq M_p \\
\langle p, u \rangle & \leq M_d
\end{align*} \quad t \geq 1
$$

(4.7.2)

Assuming that the LP-system is P-or D-directed, substitution of (4.7.1) and (4.7.2) in (4.3.1) or (4.4.1) gives the inequalities:

$$
\sum_{t=1}^T \langle p(t), (x(t), y(t)) \rangle \leq M_d - M_p, \quad t \geq 1
$$

(4.7.3)
Since $\Phi, w, (\xi, \eta)$ and $(u, v)$ are all positive, the inequalities (4.7.3) imply that $\beta \leq 1$.

4.6 Remark.

Henceforth we shall mainly consider the situation that $\beta \leq 1$.

In that case, for every $p$-dominated $x \in \mathbb{R}^n$ and every $p$-dominated $w \in \mathbb{R}^n_+$, $x \in \mathbb{R}^n_+$ and $w \in \mathbb{R}^n_+$.

Since $T \leq 1$ and $p \leq 1$, this implies that, for every $p$-dominated $p$-feasible $x$ and for every $p$-dominated $D$-feasible $u$, the sequences $(p_{\eta}, x^\eta)_{T=1}^\infty$ and $(p_{\eta}, u^\eta)_{T=1}^\infty$ resp. are convergent.

4.7 Theorem.

A $p$-feasible solution $x$ of a LP-system ($p$-or $D$-directed; $p$-feasible; $D$-regular; $\beta \leq 1$) is consistent if and only if $x \in \mathbb{R}^n_+$.

Proof.

Necessary: Let $M$ be a lower bound for the primal partial objective function of a $p$-consistent solution $x$ and let $(u, v)$ be a $D$-regular solution.

Since the LP-problem is $p$-or $D$-directed the theorems 4.3 or 4.4 imply:

\[
\sum_{T=1}^\infty \sum_{\eta=1}^p v(t)^\eta x(t) \leq \sum_{T=1}^\infty \sum_{\eta=1}^p f(t)^\eta u(t) \leq M \quad \text{for all $u, v$.}
\]

where the last inequality follows from the fact that $u, v \leq 1$ and $\beta \leq 1$.

Since $v \leq 1/\gamma \in \text{int}(1^\infty_\gamma)$ and $w \in \mathbb{R}^n_+$, the inequalities (4.8.1) imply:

$x \in \mathbb{R}^n_+$.

Sufficient: Let $x$ be a $p$-feasible solution such that $x \in \mathbb{R}^n_+$.
Since \( p \in \mathcal{N} \), this supposition implies:

\[
\langle v, x \rangle - P \geq 1 \quad \text{for all } t \geq 1.
\]

Clearly, \( x \) is consistent.

4.10 Theorem.

A D-feasible solution \( u \) of a LP-system (P- or D-directed; P\textsuperscript{D}-regular; D-feasible; \( \text{D} \leq 1 \)) is consistent if and only if \( v \in \mathcal{N} \).

Proof.

This theorem may be proven in a similar way as theorem 4.9.

4.11 Remark.

Up to now it always has been supposed that the primal and dual systems are both feasible. Now, however, we shall start from suppositions implying that one of the systems is not feasible.

4.12 Proposition.

If, for a LP-system (D-consistent) a period \( T \geq 1 \) exists, such that the system of linear inequalities

\[
\begin{align*}
Bx(t) & \leq Pf(t) + Ax(0) \\
Bx(t+1) - Ax(t) & \leq \rho x(t+1), \quad t=1,2,\ldots,T \\
x(t) & \geq 0, \quad t=1,2,\ldots,T+1
\end{align*}
\]

(4.12.1)

is nonsolvable, then a lower bound for the dual partial objective functions does not exist.

Proof.

If (4.12.1) is nonsolvable, then, by virtue of
Farkas' theorem (*) it follows that a \( \{u^0(t)\}_{t=1}^{T+1} \), \( u^0(t) \geq 0, \) \( t=1,2,\ldots,T+1 \) exists, satisfying

\[
\begin{align*}
2'\nu(t)-\alpha'\nu(t+1) & \leq \varepsilon, \quad t=1,2,\ldots,T \\
\beta'u(t+1) & \geq 0 \\
\nu(\theta) & < 0
\end{align*}
\]  

(4.12.2)

Now let \( \hat{u} \) be a \( \mathcal{D} \)-consistent solution and let us define the vectors \( u(\lambda) := \{u(t;\lambda)\}_{t=1}^{T+1} \) for every \( \lambda \geq 0 \) by

\[
\begin{align*}
u(t;\lambda) := & \hat{u}(t) + \lambda \nu(t), \quad t=1,2,\ldots,T+1 \\
\nu(t;\lambda) := & \hat{u}(t), \quad t>T+1
\end{align*}
\]  

(4.12.3)

Then (4.12.2) and (4.12.3) imply that the vectors \( u(\lambda), \lambda \geq 0 \) are all feasible and, moreover, that

\[
\langle \nu^0, u(\lambda) \rangle = \langle \nu^0, \hat{u} \rangle + \lambda \langle \nu^0, \nu^0 \rangle_{T+1} > 0, \quad \lambda \geq 0.
\]

Since it is supposed that \( \hat{u} \) is \( \mathcal{D} \)-consistent and since

\[
\langle \nu^0, u^0 \rangle_{T+1} < 0,
\]

we can conclude that \( u \) lower bound for the dual partial objective functions does not exist.

4.3 Proposition.

If for a LP-system (\( \mathcal{P} \)-consistent) a period \( T \geq 1 \) exists, such that the system of linear inequalities

\[
\begin{align*}
\beta'u(t) - \alpha'u(t+1) & \geq \varepsilon p(t), \quad t=1,2,\ldots,T \\
u(t) & \geq 0, \quad t=1,2,\ldots,T+1
\end{align*}
\]  

(4.13.1)

is nonsolvable, then an upper bound for the primal partial objective functions does not exist.

(*) Farkas' theorem (inequality form): The system of linear inequalities \( \mathcal{A}x \leq b \) has a solution \( x \leq 0 \) if and only if every \( u \geq 0 \) satisfying \( \mathcal{A}'u \geq 0 \) also satisfies \( \mathcal{B}'u = 0 \).
5. INFERIORITY.

5.1 Introduction.

In this chapter we shall derive some properties with respect to the concept of inferiority. We repeat the definition already given at §2.5.

A P-feasible solution \( \bar{x} \) is called inferior with respect to a P-feasible solution \( \tilde{x} \), if an \( \epsilon > 0 \) and a period \( \tau \geq 1 \) exist such that

\[
\langle \tilde{x} \rangle_s \leq \langle \bar{x} \rangle_s - \epsilon, \quad s > \tau
\]  

(5.1.1)

A U-feasible solution \( u \) is called inferior with respect to a U-feasible solution \( \tilde{u} \), if an \( \epsilon > 0 \) and a period \( \tau \geq 1 \) exist such that

\[
\langle u \rangle_s \geq \langle \tilde{u} \rangle_s + \epsilon, \quad s > \tau.
\]  

(5.1.2)

5.2 Theorem.

For every P-consistent solution \( \bar{x} \) of a LP-system (P or U-directed; P-consistent; U-regular; P X 1), a number \( M \geq \| \bar{x} \|_1 \), exists such that every P-feasible \( \bar{x} \), with the property that

\[
\| \bar{x} \|_1 \geq M, \quad \text{for some} \; \tau \geq 1,
\]  

(5.2.1)

is inferior with respect to \( \bar{x} \).

Proof.

Let \( (u, \tilde{u}) \) be a U-regular solution, then proposition 4.3 or 4.4 implies:

\[
\langle u \rangle_s - \langle \tilde{u} \rangle_s \geq \langle \bar{v} \rangle_s, \quad s > 1
\]  

(5.2.2)

for every P-feasible solution \( x \). Since \( \tilde{u} \in \text{int}(\mathbb{R}^n) \), it
follows from (5.2.2) that a number \( N_1 > 0 \) exists such that

\[
\langle P_0, x \rangle_{S^1} \leq F_0^0 \| x \|_{S^1} + \| u_1 \|_{S^1} - N_1 \| x \|_{S^1} \leq 0, \quad S \geq 1
\]  

(5.2.3)

for every \( P \)-feasible \( x \).

Let \( x \) be a \( P \)-consistent solution, then (5.1.1) a number \( N_2 > 0 \) exists such that

\[
\langle P_0, x \rangle_{S^1} \leq N_2, \quad S \geq 1.
\]  

(5.2.4)

From (5.2.3) and (5.2.4) we may conclude that for every \( P \)-feasible \( x \):

\[
\langle P_0, x \rangle_{S^1} \leq F_0^0 \| x \|_{S^1} + \| u_1 \|_{S^1} + N_2 \| x \|_{S^1} \leq 0, \quad S \geq 1.
\]  

(5.2.5)

Putting \( M = \frac{F_0^0 \| x \|_{S^1} + \| u_1 \|_{S^1}}{N_1} \) or \( M_1 \), then (5.2.5) implies

\[
\langle P_0, x \rangle_{S^1} \leq M_1 (M_{1, N_1} \| x \|_{S^1} + T), \quad S \geq 1
\]  

(5.2.6)

for every \( D \)-feasible \( x \).

From (5.2.6) we may conclude:

- \( \| x \|_{S^1} \leq M_1 \),
- every \( P \)-feasible \( x \), satisfying (5.2.1) for some \( T \geq 1 \) is inferior with respect to \( \tilde{u} \).

5.3 Theorem.

For every \( D \)-consistent solution \( \tilde{u} \) of the \( P \)-system (\( D \)-directed; \( D \)-consistent; \( P \)-regular; \( \sigma < 1 \)), a number \( M \geq \| u_1 \|_{S^1} \) exists such that every \( D \)-feasible \( u \), with the property that

\[
\| u \|_{S^1} \leq M, \quad \text{for some } T \geq 1
\]  

(5.3.1)

is inferior with respect to \( \tilde{u} \).
Proof.

This theorem follows from 5.2 and from the symmetry between the primal and dual systems.

5.4 Definitions.

We consider the LP-system

\[ \begin{align*}
Bx(t) & \leq \beta f(t)+Az(0) \\
Bx(t+1)-Ax(t) & \leq \rho^{t+1}f(t+1), \quad T \geq 1 \\
<\phi_{\pi},w_{A}> & = \sum_{t=1}^{T} \sigma_{t}p(t)x(t), \quad T \geq 1 \\
<\phi_{\pi},w_{A}> & - \sum_{t=1}^{T} \sigma_{t}f(t), \quad T \geq 1 \\
B'u(t)-A'u(t+1) & \leq \sigma_{t}f(t), \quad T \geq 1 \\
<\phi_{\pi},w_{A}> & - \sum_{t=1}^{T} \sigma_{t}f(t), \quad T \geq 1
\end{align*} \]

for all vectors \(x(0), f \) and \( p \) from neighbourhoods \( U(h)C_{\pi}^{\rho}, \)
\( \Omega(\rho)C_{\pi}^{\rho} \) and \( \Omega(\pi)C_{\pi}^{\pi} \) of vectors \( h \in \mathbb{R}_{+}, \)
\( q \in \mathbb{R}_{+} \) and \( \sigma \in \mathbb{R}_{+} \), further to be described.

With regard to the fixed matrices \( A \) and \( B \), we suppose that they are such, that a \( f \) or \( p \) exists for which the LP-system (5.4.1) is \( P \)- or \( D \)-directed. For the fixed quantities \( \rho \) and \( \pi \), it is supposed that \( \rho \sigma < 1 \).

With regard to the vectors \( h \in \mathbb{R}_{+}^{n}, q \in \mathbb{R}_{+}^{m} \) and \( q \in \mathbb{R}_{+}^{n} \), we suppose that the following conditions are met:

a) for \( x(0)=h, f=q \) and \( p=q \), the LP-system (4.1.5) is \( P \)- directed and \( D \)-regular,

b) a number \( h \geq 1 \) and vectors \( (x,y) \in \mathbb{R}^{n} \times \mathbb{R}^{m}, (\tilde{u},\tilde{v}) \in \mathbb{R}^{m} \times \mathbb{R}^{n} \) exist, such that for \( \{x,y\} \in \mathbb{R}_{+}^{n} \times \mathbb{R}_{+}^{m}, \{\tilde{u},\tilde{v}\} \in \mathbb{R}_{+}^{m} \times \mathbb{R}_{+}^{n} \), and

\[ \begin{align*}
B_{\pi}(t+1)-A_{\pi}(t)+\gamma(t)=\rho^{t+1}f(t+1) \\
B'u(t)-A'u(t+1) = \gamma(t) \quad T \geq 1
\end{align*} \]
for some period \( K \geq 1 \).

Clearly, in that case, neighbourhoods \( \Omega(h) \subseteq \mathbb{R}_+^n \), \( \Omega(q) \subseteq \mathbb{R}_+^m \), and positive numbers \( \delta_1 \) to \( \delta_4 \) exist, such that for every \( x(0) \in \Omega(h) \), it \( \in \Omega(q) \) and \( p \in \Omega(t) \):

c) \( B^\Delta x(t+1) - A^\Delta x(t) - (B\delta_1)^{t+1} \delta_{1,2} \geq \sum p(t+1), \ t \geq K, \) (5.4.3)

d) \( B^\Delta x(t) - A^\Delta x(t) - (B\delta_1)^t \delta_{1,2} \geq \sum p(t+1), \ t \geq K, \) (5.4.4)

\( \Delta, \Omega, \beta, K \), being the same quantities as appearing in b).

d) \( B^\Delta x(t) - A^\Delta x(t) - (B\delta_1)^{t+1} \delta_{1,2} \leq \sum p(t+1), \ t \geq K, \) (5.4.5)

for some fixed \( \delta_1 > 0 \), \( \sum \beta \), such that \( \Delta \subseteq \mathbb{R}_+^n \) and \( \Omega \subseteq \Omega \).

In the following properties the equalities (3.6.1) and (3.4.5) will be used to construct, from every given \( P \)-feasible solution, a sequence of substitute \( P \)-feasible solutions. Next a comparison will be drawn between the values of the corresponding objective functions.

We define:

e) \( \Omega(g) := \{(f(0), f(1), f(2), \ldots, f(t) | x(0) \in \Omega(h), x(0) \in \Omega(q), x(t) \in \Omega(t)\} \)

where: \( g := \{g(1), g(2), \ldots, g(t), \ldots\} \).

f) For every \( f(0) \in \mathcal{G}^T_{\Omega}(g) \), \( z \in \mathbb{R}^m \) the set:

\[ X(f^0, z) := \left\{ \begin{array}{ll}
\Delta x(1) & \geq \sum p(1) + x(1) \\
n_k & \geq \sum (t+1) + x(t+1) + z(t+1), t \geq 1
\end{array} \right\} \]

\( \Delta \) is the sequence of numbers \( \delta(t) := \delta(t; t) \) for \( t = 0, 1, \ldots, K-1 \) and \( \delta(t) := \delta(t; t) \) for \( t = K-1 \).
\[ \dot{\theta}(t;T) = \begin{cases} 1 & t = 1, T \\ 0 & t \neq 1, T \end{cases} \]

in case that \( K = 1 \),

\[ \dot{\theta}(t;T) = 0, t > T \]

\[ \dot{\theta}(K-1;T) = 1 \]

\[ \dot{\theta}(t;T) = -\beta^{-(T+1)} \beta^{-(K+1)} \]

in case that \( K > 1 \),

\[ \dot{\theta}(t;T) = 0, t > T \]

\[ \dot{\theta}(t;T) = \beta^{-(T+1)} \]

in both cases.

b) For every \( x \in \mathbb{R}(g^{0}, l_{\infty}^{m}) \) and every \( t \in \mathbb{R} \), the vectors \( \dot{x}(t;T) \) and \( \dot{\dot{x}}(t;T) \) are defined by:

\[ \dot{x}(t;T) = \dot{x}(t), \quad t = 1, 2, \ldots, K-1, \quad \text{provided } K > 1 \]

\[ \dot{x}(t;T) = x(t) + \dot{\theta}(t;T)(1-\dot{\theta}(t;T)) \dot{x}(t) + \dot{\theta}(t;T) \dot{\dot{x}}(t) \]

where \( \Lambda \) is the diagonal non-negative matrix as defined in proposition 3.5, and \( \dot{x} \) is the vector of property 5.4-c.

5.5 Proposition:

If the vectors \( x \in \mathbb{R}^{m} \), \( g^{0} \) and \( q^{0} \) satisfy the conditions 5.4-a, b, then neighbourhoods \( \mathcal{N}(h) \subset \mathbb{R}^{m} \), \( \mathcal{G}(g) \subset \mathbb{R}^{m} \), \( \mathcal{G}(q) \subset \mathbb{R}^{m} \) and positive numbers \( \varepsilon \), \( \delta \) exist such that:

for every \( (f, p) \in \mathcal{G}(g) \times \mathcal{G}(q) \), for which the LP-system (5.4.1) is \( \Theta \)-directed, and for every \( x \in \mathbb{R}^{m} \), the vectors \( \dot{x}(T;T), T \in \mathbb{R} \), \( \dot{x}(f^{0}, x) \) as defined by 5.4-b, possess the following properties:

a) In case \( K = 1 \):

\[ \dot{x}(t+1;T) = \dot{x}(t;T) + \beta^{-(T+1)} \dot{x}(t) + \delta^{-(T+1)} \dot{x}(t) \]

\[ \dot{x}(t+1;T) = \dot{x}(t;T) + \beta^{-(T+1)} \dot{x}(t) + \delta^{-(T+1)} \dot{x}(t) \]
b) In case $x \geq 1$:

\[
\begin{align*}
B_1(t; \tau, x) & \leq \delta f_1(x(t) + x(t+1)) \\
B_2(t+1; \tau, x) & - A \delta(t; \tau, x) \leq \Delta f_2 \delta(t+1) \geq 0(t+1) + x(t+1), t \geq 1, t \neq K-1 \\
B_3(0; \tau, x) & - A \delta(K-1; \tau, x) \\
& + B \delta(T-1) \delta(K) \geq 0 \delta(K) + x(K)
\end{align*}
\] (5.5.2)

c) In both cases, if $x_{\delta-1} \in \mathbb{N}$:

\[
\Delta(t; \tau, x) := \left< \delta \rho, \Delta(t; \tau, x) \right> \leq \left< \delta \rho, \Delta(t; \tau, x) \right> \leq
\]

\[
\begin{align*}
& - B \delta(T-1) \delta(K) + \delta(T-1) \delta(K) - \delta(T-1) \delta(K) \\
& + \delta(T-1) \delta(K) - \delta(T-1) \delta(K) + \delta(T-1) \delta(K)
\end{align*}
\] (5.5.3)

Proof.

As has been explained in §5.4, there are neighbourhoods, $S(h) \subset N_h, S(g) \subset N_h, S(q) \subset N_h$ for the vectors $h, g, q$ satisfying 5.4-a, b, for which the properties 5.4-c, d hold. In the proof we shall further depart from these neighbourhoods.

(a) and (b): Since the sequences $\{S(t; \tau, x)\}_{t=1}^{\infty}$ and $\{\tilde{S}(t; \tau, x)\}_{t=1}^{\infty}$ (5.4-g) are monotonous non-increasing, proposition 3.5 implies: for every $x \ni (f; \tau, x)$ (def 5.4-f), provided $x \ni (f; \tau, x)$ and $(f; \tau, x) \ni (f; \tau, x)$ such that the LP-system (5.4.1) is P-or D-directed, the following inequalities hold:

\[
\begin{align*}
S(t; \tau, x) & \leq \delta(0(t; \tau, x)(1-x))x(t+1) \\
- A(0(t; \tau, x)(1-x))x(t) & \leq \delta(0(t; \tau, x)(1-x))x(t+1), t \geq 1
\end{align*}
\] (5.5.4)

Moreover, for $x$ (5.4-c) we have:
\[ \hat{x}(t+1;T) = \hat{x}(t;T) + \hat{x}(t;T)(I-\lambda) \hat{x}(t+1) - \hat{x}(t;T)(I-\lambda) x(t) \hat{x}(t;T)(\beta^t) x(t+1), \]
\[ t \geq T_x. \]  

From (5.5.4), (5.5.5), \( x \in L^2 \) and from the definitions (5.4-2,3,4,5) of \( \hat{x}(t;T), \hat{x}(T), \) and \( \hat{x}(T) \), it follows:

\[ \Delta x(t+1;T) = -\hat{x}(t;T)(I-\lambda)^{K+1} x(t+1), t \geq T_x. \]  

The validity of the properties a) and b) is further deduced from the above, with the help of the definition of \( \hat{x}(t;T), \hat{x}(T) \) and \( \hat{x}(T) \).

(c): Defining

\[ \rho^\lambda := (\Delta \rho(t)) \frac{1}{(I-\lambda)}, \]

for every \( \rho \in \mathbb{C}^q \), the definition of \( \hat{x}(t;T) \) (5.4-1) implies that \( \Delta x(t;T) \) may be expressed as follows:

- In case \( T=1, T \geq K \):

\[ \Delta x(t;T) = \hat{x}(T) \rho x(t;T) + \hat{x}(t;T) x(t;T) \rho^T \Delta \rho(T+1) x(t+1;T), T \geq 1, \]

\[ = \langle \rho_x, x \rangle_{T+1, T} + \hat{x}(T) \rho x(t;T) \Delta x(T+1) x(t+1;T), T \geq 1. \]  

- In case \( T=K=1 \), the second term of the right-hand side of (5.5.6) will be cancelled.

- In case \( T > K > 1 \):

\[ \Delta x(t;T) = \hat{x}(T) \rho x(t;T) + \hat{x}(t;T) x(t;T) \rho^T \Delta \rho(T+1) x(t+1;T), T \geq 1, \]

\[ - \langle \rho_x, x \rangle_{K, T} - \hat{x}(T) \rho x(t;T) \Delta x(T+1) x(t+1;T), T \geq 1. \]  

For arbitrary \( (x(0), x, \rho) \in \mathbb{C}^q \times (\mathbb{C}^q)^2 \times \mathbb{C}^q \), \( x \in L^2 \), \( \rho \in \mathbb{C}^q \) and
L > T_m^2, such that:
- the LP-system (5.4.1) is $P$-or $D$-directed,
- $|x(x) - b| \leq \varepsilon_1, |f - g| \leq \varepsilon_1, |p - q| \leq \varepsilon_1$,
- $\exists \delta \in \delta_{\varepsilon_1}$.

The terms of the right-hand side of (5.5.8) and (5.5.9) will be valued down with the help of positive numbers $M_1$ to $M_8$, which are independent of $x, L$ and $T$. We shall first consider (5.5.8).

The first three terms of the right-hand side of (5.5.8).

First we put the case that $f^0$ is such that the LP-system (5.4.1) is not $P$-directed and so is $D$-directed.

Then, the definitions of $\Lambda$ (3.5) and $p^\Lambda$ (5.5.7) imply:

\[
\begin{align*}
\begin{bmatrix}
p^\Lambda \in m_n \\
BA \geq 0 \\
A(1 - \Lambda) \geq 0
\end{bmatrix}
\end{align*}
\]

(5.5.10)

Denoting the sum of the values of the first three right-hand side terms of (5.5.8) by $\Delta_1(L, T, x)$, then (5.5.10) and the fact that $\delta > 1$ and $x \in \Delta_1^n$ imply:

\[
\Delta_1(L, T, x) \leq K \delta \delta^{X - X} X(k) \langle p_x, \delta - 1 \rangle \delta^{X + 1, 2} + \langle \delta \delta^{X - X} p, p \rangle \xi \xi^0, L.
\]

(5.5.11)

The second term of the right-hand side will be cancelled when $T = 1$.

We shall value down the right-hand side of (5.5.11) for the case that $T = 1$.

Since $\omega(x, f^0, x)$ and $\delta > 1$, it follows from (5.5.10) that
\[ B^{(r+1)} \begin{bmatrix} x(t) \\ x(t+1) \end{bmatrix} \leq \begin{bmatrix} B & 0 \\ A & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ x(t+1) \end{bmatrix} + \begin{bmatrix} \delta^{T+1} f(t) \\ \delta \end{bmatrix}, \quad t = K, K-1, \ldots, 1 \]

\[ B(\gamma^{-1} I - \Lambda) x(t+1) = -A B^{(r+1)} \delta \]

\[ \leq \begin{bmatrix} B & 0 \\ A & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ x(t+1) \end{bmatrix} + \begin{bmatrix} \delta^{T+1} f(t+1) \\ \delta \end{bmatrix}, \quad t = K, K-1, \ldots, 1 \]

\[ (5.5.12) \]

Denoting \( \gamma, \gamma_1 \in \mathbb{R}^n \) and \( \delta \geq 0 \) as the quantities for which property (5.4.6) holds, then:

\[ \begin{bmatrix} B^{(r+1)} \delta^{T+1} f(t) p(x) \\ \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta \end{bmatrix} \leq \begin{bmatrix} B^{(r+1)} \delta^{T+1} f(t) p(x) \\ \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta \end{bmatrix}, \quad t = K \]

\[ (5.5.13) \]

in which the first inequality follows from the supposition that the LP system (5.4.1) is \( \delta \)-directed.

The whole, consisting of (5.5.12) and (5.5.13), may be taken as on LP system which is \( \delta \)-directed. By applying proposition 4.4 on this LP system, one can derive the following inequality:

\[ \begin{bmatrix} B^{(r+1)} \delta^{T+1} f(t) p(x) \\ \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta \end{bmatrix} \leq \begin{bmatrix} B^{(r+1)} \delta^{T+1} f(t) p(x) \\ \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta \end{bmatrix}, \quad t = K, K-1, \ldots, 1 \]

\[ \leq \begin{bmatrix} B^{(r+1)} \delta^{T+1} f(t) p(x) \\ \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta \end{bmatrix}, \quad t = K, K-1, \ldots, 1 \]

Since \( \| \xi \|_2 \leq 1 \), \( \gamma, \gamma_1 \in \mathbb{R}^n \), \( \delta \geq 1 \), and \( \xi_0 \in \mathbb{R}^n \), one can derive from the latter inequality, that positive numbers \( \gamma_1 \) to \( \gamma_2 \) exist such that:

\[ \delta_1(\xi, T, K) \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} (\gamma^{-1} I - \Lambda) x(t) + \begin{bmatrix} \beta^{(r+1)} - \beta \end{bmatrix} \delta, \quad t = K, K-1, \ldots, 1 \]

\[ (5.5.14) \]

For the case that \( K = \infty \), the same inequality will be found.
Now consider the case that \( f^0 \) is such that LP-system (5.4.1) is \( P \)-directed. Then, \( \Lambda \) is defined as the identity matrix; hence:

\[
\delta_{\Lambda}(L,T,x) = e^{-T} \langle P, x \rangle e^{-T} \langle P, x \rangle_T - e^{-T} \langle P, x \rangle_{T+1}.
\]

Exploring the properties of \( P \)-directed LP-systems already deduced, the right-hand side of latter equality may be valued down in a similar manner as done above.

The fourth and fifth term of the right-hand side of (5.5.8)

Since, by assumption,

\[
\begin{align*}
\beta &< 1 \Rightarrow \eta = 1, \\
\eta &< 1 \Rightarrow \alpha, \\
\alpha &< 1,
\end{align*}
\]

we may conclude that positive numbers \( M_6 \) and \( M_7, \) exist such that

\[
\begin{align*}
- &\beta^{-1} \langle p, x \rangle, \\
(1 - p - \rho) &\eta = \beta e^{-T} \langle P, x \rangle_T - e^{-T} \langle P, x \rangle_{T+1, L} \\
&\leq \rho^{-1} \langle p, x \rangle - (\beta \eta) e^{-T} \langle P, x \rangle_{T+1, L},
\end{align*}
\]

(5.5.15)

The total right-hand side of (5.5.8)

By substitution of (5.5.14) and (5.5.15) in (5.5.8) we may deduce that property c) holds in case \( K = 1. \)

The right-hand side of (5.5.9)

We may treat the right-hand side of (5.5.9) in a similar manner as the right-hand side of (5.5.8); i.e., (5.5.11) will change into

\[
\begin{align*}
\delta_{\Lambda}(L,T,x) &= e^{-T} \langle P, x \rangle e^{-T} \langle P, x \rangle_T - e^{-T} \langle P, x \rangle_{T+1, L},
\end{align*}
\]

and consequently, (5.5.13) takes the form

\[
\beta^\gamma (u(t) - B\gamma^{-1} u(t+1)) - e^{-T} \langle P, x \rangle_T - \beta \alpha \gamma^{-1} p(z), \quad \gamma \in \mathbb{R}.
\]
5.6 Proposition.

If the vectors $b \in \mathbb{R}^n$, $g \in \mathbb{R}^m_n$ and $q \in \mathbb{R}^m_n$ are such that the LP-system (5.4.1) is P- or D-directed and P- or D-regular for $x(0) = h$, $f=q$ and $p=q$, then $\delta \in \mathbb{R}^n$ exists for which the following holds:

For every \( \delta \in \mathbb{R}^n \), neighbourhoods $U(h) \subset E^m_n$, $U(q) \subset E^m_n$, and positive numbers $N_1$, $N_2$ exist such that, for every $x(0) \in U(h)$ and every $(t, p) \in U(q) \times U(q)$ for which the LP-system (5.4.1) is P- or D-directed, the following property holds:

If \( \delta \in \mathbb{R}^n \) for some $\delta$, satisfies:

\[
\begin{align*}
Bx(1) & \leq f(1) + Ax(0) + z(1) \\
Bx(t+1) - Ax(t) & \leq f(t+1) + z(t+1), \quad t \geq 1 \\
|x(t)|_{\beta_1}^m + |x(t)|_{\beta_2}^m & \leq N \quad \text{for some } T \leq 1
\end{align*}
\]

then, an $\varepsilon > 0$, $T > 1$, and $x_k \in \mathbb{R}^m_n$, exist satisfying:

\[
\begin{align*}
Bx_k(1) & \leq f(1) + Ax(0) + z(1) \\
Bx_k(t+1) - Ax(t) & \leq f(t+1) + z(t+1), \quad t \geq 1 \\
|x_k(t)|_{\beta_1}^m + |x_k(t)|_{\beta_2}^m & \leq N \quad \text{for some } T \leq 1 \\
& < \varepsilon \quad \text{for some } \varepsilon < \varepsilon
\end{align*}
\]

Proof.

We denote $((x, y), (\tilde{u}, \tilde{v}))$ as a P- and D-regular solution of the LP-system (5.4.1) with $x(0) = h$, $f=q$ and $p=q$. Since $\tilde{u} / P \in \text{Int}(E^m_n)$ and $\tilde{v} / P \in \text{Int}(E^m_n)$, a $\delta \in \mathbb{R}^n$ exists (close enough to 1) such that for every $\delta \in \mathbb{R}^n$, property 5.4-6 holds, with $h = \text{Int}(E^m_n)$, $x \in \mathbb{R}^m_n$, and $\tilde{u} = \text{Int}(E^m_n)$. Hence the conditions of proposition 5.5 are satisfied for every $\delta \in \mathbb{R}^n$. Note $\tilde{U}(h) \subset E^m_n$, $\tilde{U}(q) \subset E^m_n$, and $\tilde{U}(q) \subset E^m_n$ as bounded neighbourhoods of $h$, $g$ and $q$ respectively, belonging to certain $\delta \in \mathbb{R}^n$ for which
the properties 5.5-a, b, c hold. Moreover, we choose these
neighbourhoods in such a manner that positive numbers \( \delta_1 \) to
\( \delta_4 \) exist such that \( \hat{x} = \mathbb{B}_{\delta_1} \), \( \hat{u} = \mathbb{B}_{\delta_2} \), \( \hat{x} \) and \( \hat{u} \) resp. satisfy
(5.4.3) to (5.4.6) for all \((u(0), t, p) \in G(h) \times G(g) \times G(q)\).

With the help of the set \( G(g) \) as defined in 5.4-a, we put
\( G(g, q) \) as the set of vectors \((f^0, p) \in G(g) \times G(q)\) for which
IF-system (5.4.1) is P or D-directed.

Defining, for every \( u \in G(g, 1^t) \) (def. 5.4-f) and \( T \in \mathbb{N} \), the
vectors \( \hat{x}(t, x) \) as in 5.5-h with \( \hat{x} = \mathbb{B}_{\delta_3} \), then, for all
\((f^0, p) \in G(g, q)\), \( x \in 1^t \) and \( u \in 1^t \), \( \hat{x} \in 1^t \), satisfying:

\[
\begin{align*}
Bx(1) & : \hat{x}(t+1) = f^0(t+1) + u(t+1), \\ Bx(1) & : \hat{x}(t+1) = f^0(t+1) + u(t+1), \quad t \geq 1
\end{align*}
\]

the following three properties hold:

**Property 1**
the vectors \( \hat{x}(t, x) \) \( T \) satisfy:

\[
\begin{align*}
B_0 \hat{x}(1,t,x) & : \hat{x}(t+1) = f^0(t+1) + u(t+1), \\ B_0 \hat{x}(1,t,x) & : \hat{x}(t+1) = f^0(t+1) + u(t+1), \quad t \geq 1
\end{align*}
\]

This follows from 5.5-a and from the fact that \( \hat{x} = \mathbb{B}_{\delta_3} \).

**Property 2**

\[
\begin{align*}
\hat{x}(t,x) & \in 1^t, \quad T \geq 1, \\
\hat{x}(t,x) & \in 1^t, \quad T \geq 1 \\
\hat{x}(t,x) & \in 1^t, \quad T \geq 1
\end{align*}
\]

This property follows from the definition of \( \hat{x}(t, x) \) (5.4-h)
and from the fact that \( \hat{x} = \mathbb{B}_{\delta_4} \in 1^t \), \( \hat{u} \in 1^t \), \( u \in 1^t \).
Property 3

Positive numbers \( N_1 \), \( N_2 \) and \( N_3 \), which are independent of \( x \), \( f^0 \), \( \theta \) and \( z \), exist, such that

\[
\langle \mathbf{p}_n, \mathbf{x}_L \rangle - \langle \mathbf{p}_n, \bar{\mathbf{x}}(T, x) \rangle \leq \tilde{c} \cdot T \mathbf{g}^{-T} \left( -N_1 I_{\mathcal{G}^0 [1]} + N_2 1_{\mathcal{G}^0 [1]} - N_3 1_{\mathcal{G}^{0} [1]} \right)
\]

\( T \geq 1 \), \( L \geq 2 \).

This follows from (5.5-9) and from the fact that \( \mathcal{G}^0 [1] \) is a vector of the bounded set \( \mathcal{U}(n) \).

Now, define the positive numbers \( N_1 \) and \( N_2 \) by

\[
\begin{cases}
N_1 = \frac{M_2}{M_1 + z_0} \\
N_2 = \frac{M_3}{M_1}
\end{cases}
\]

and suppose that \( \mathbf{p}^0 \) for certain \( (f^0, p) \in \mathcal{S}(\mathbf{g}^0, q) \) and \( z \), \( \mathbf{p}^0 \) satisfies (5.6.1).

Defining for this \( x \) a period \( \bar{\gamma} \) by

\[
\bar{\gamma} = \min_{T > 0} T \left| \mathbf{g}^0 [1] \mathbf{I} + T \mathbf{M}_1 - \mathbf{M}_1 - \mathbf{M}_2 \right|
\]

then, from (5.6.9), (5.6.10), and from the fact that, for some \( T \geq 1 \), \( T \mathbf{g}^{0} [1] \mathbf{I} + T \mathbf{M}_1 - \mathbf{M}_1 - \mathbf{M}_2 \), it follows that \( \bar{\gamma} \).

First consider the case that \( \gamma = 1 \). Then, (5.6.10) and property 3 imply that an \( \mathbf{e}_3 > 0 \) exists such that

\[
\langle \mathbf{p}_n, \mathbf{x}_L \rangle - \langle \mathbf{p}_n, \bar{\mathbf{x}}(1, x) \rangle \leq \tilde{c}, \quad L \geq 2.
\]

property 2) and definition (5.6.9) imply:

\[
\Lambda_{+} (1, x) \mathbf{e}_3 \mathbf{I} = \mathbf{u}_0 \mathbf{I} + \mathbf{u}_0 \mathbf{I} + \mathbf{u}_0 \mathbf{I}
\]

\[
\mathbf{u}_0 (1, x) \mathbf{g}^{0} [1] = N_1 N_2 \mathbf{I} \mathbf{e}_3 \mathbf{I}
\]

From (5.6.11), (5.6.12) and from property 1) we may conclude that \( x \mathbf{u} = \mathbf{x}_L (1, x) \) satisfies (5.6.2) for every \( L \geq 2 \).
Now, consider the case that $\tau = 1$. Then, (5.6.10) and property 3) imply that an $e > 0$ exists such that

$$
< P_{\mathbf{c}}, x_{\mathbf{L}} > < P_{\mathbf{c}}, x_{(\tau - 1, x)} > L_{\mathbf{L}} \leq e, \quad \mathbf{L} = \tau + 1.
$$

(5.6.12)

Property 2) and the definitions (5.6.9) and (5.6.10) imply:

$$
\mathbf{x}_{(\tau - 1, x)} \in \mathbf{N}_{\mathbf{1}}^{\mathbf{1}} + \mathbf{K}_{\mathbf{1}}^{\mathbf{1}}
$$

(5.6.13)

From (5.6.13), (5.6.14), and for property 1), we may conclude that $\mathbf{x} = \mathbf{x}_{(\tau - 1, x)}$ satisfies (5.6.2) for every $\mathbf{L} = \tau + 1$.

5.7 Theorem

If $h \in \mathbf{E}_{\mathbf{m}}$, $\mathbf{g} \in \mathbf{Q}_{\mathbf{m}}$, and $\mathbf{q} \in \mathbf{Q}_{\mathbf{m}}$ are such that the LP-system (5.4.1) is $F$-or $D$-directed and $F$-or $D$-regular for $\mathbf{x}(0) = h$, $\mathbf{f}(0) = \mathbf{g}$, and $\mathbf{p} = \mathbf{q}$, then a $\mathbf{S} \subseteq \mathbf{1}, \mathbf{L} / \mathbf{D}$ exists for which the following holds:

For every $\mathbf{D} \subseteq \mathbf{1}, \mathbf{S}$, neighbourhoods $\mathbf{N}(\mathbf{h}) \in \mathbf{E}_{\mathbf{m}}$, $\mathbf{N}(\mathbf{g}) \in \mathbf{Q}_{\mathbf{m}}$, $\mathbf{N}(\mathbf{q}) \in \mathbf{Q}_{\mathbf{m}}$ and positive numbers $\mathbf{N}_{\mathbf{1}}$ and $\mathbf{N}_{\mathbf{2}}$ exist such that, for every LP-system (5.4.1; $\mathbf{x}(0), \mathbf{f}, \mathbf{p} = \mathbf{Q}(\mathbf{h}) \times \mathbf{Q}(\mathbf{g}) \times \mathbf{Q}(\mathbf{q});$ $F$-or $D$-directed) the following properties hold:

a) For every $F$-feasible solution $\mathbf{x}$ such that

$$
\mathbf{x} \in \mathbf{S} \subseteq \mathbf{1}, \mathbf{T} \ni \mathbf{N}_{\mathbf{1}}, \quad \text{for some } \mathbf{T} \ni \mathbf{1},
$$

a $F$-feasible $\mathbf{x}$ exists, such that $\mathbf{x} \in \mathbf{S} \subseteq \mathbf{1}, \mathbf{T} \ni \mathbf{N}_{\mathbf{1}}$, and such that $\mathbf{x}$ is inferior with respect to $\mathbf{x}$.

b) For every $D$-feasible solution $\mathbf{u}$ such that

$$
\mathbf{u} \in \mathbf{S} \subseteq \mathbf{1}, \mathbf{T} \ni \mathbf{N}_{\mathbf{2}}, \quad \text{for some } \mathbf{T} \ni \mathbf{1},
$$

a $D$-feasible solution $\mathbf{u}$ exists, such that $\mathbf{u} \in \mathbf{S} \subseteq \mathbf{1}, \mathbf{T} \ni \mathbf{N}_{\mathbf{2}}$, and such that $\mathbf{u}$ is inferior with respect to $\mathbf{u}$.
Proof.

By putting \( z = 0 \), this theorem follows from proposition 3.6 and from the symmetry between the primal and dual systems.

5.8 Theorem.

If the vectors \( \mathbf{h} \in \mathbb{R}^m \), \( \mathbf{g} \in \mathbb{R}^m \), and \( \mathbf{q} \in \mathbb{R}^m \) are such that the LP-system (5.4.1) is P-or D-directed and superregular for \( x(0) = h \), \( f = g \) and \( p = q \), then neighbourhoods \( \mathcal{N}(\mathbf{h}) \subseteq \mathbb{R}^m \), \( \mathcal{N}(\mathbf{g}) \subseteq \mathbb{R}^m \), \( \mathcal{N}(\mathbf{q}) \subseteq \mathbb{R}^m \) for these vectors, and positive numbers \( N_1, N_2 \) exist such that every LP-system (5.4.1) \( (x(0), f, p) \in (\mathbb{R})^m \), \( (g, q) \in (\mathbb{R})^m \); P-or D-directed) possesses the following properties:

a) For every \( P \)-feasible solution \( x \) such that

\[
\frac{1}{x} \mathbf{1}^T \mathbf{1} \geq N_1, \quad \text{for some } T \geq 1, \quad (5.8.1)
\]

a \( P \)-feasible \( x \) exists such that \( x^* \mathbf{1}^T \mathbf{1} \geq N_1 \), and such that \( x \) is inferior with respect to \( x^* \).

b) For every \( D \)-feasible solution \( u \) such that

\[
\frac{1}{u} \mathbf{1}^T \mathbf{1} \geq N_2, \quad \text{for some } T \geq 1, \quad (5.8.2)
\]

a \( D \)-feasible \( u \) exists such that \( u^* \mathbf{1}^T \mathbf{1} \geq N_2 \), and such that \( u \) is inferior with respect to \( u^* \).

Proof.

First we shall prove property a).

Since the LP-system (5.4.1) is supposed to be superregular for \( (x(0), f, p, q) = (h, g, q) \), condition 5.4-b is satisfied for some \( \beta > 0 \) (close enough to \( 1 \)). Hence, for such a \( \beta > 1 \), the conditions of proposition 5.5 are satisfied. For the sake of convenience, we put \( K = 1 \).

Notation \( \mathcal{N}(\mathbf{h}) \subseteq \mathbb{R}^m \), \( \mathcal{N}(\mathbf{g}) \subseteq \mathbb{R}^m \), and \( \mathcal{N}(\mathbf{q}) \subseteq \mathbb{R}^m \) as bounded neighbourhoods of \( h, g, q \) resp. for which the properties 5.5-a,b,c hold.

Moreover, we choose these neighbourhoods so small that pro-
property 5.4-d holds, for all $(y(o), f, p) \in \mathcal{H} \times \mathcal{G}(a) \times \mathcal{Q}(q)$, and for certain $\delta_3$, $\delta > 0$, $\tilde{x}$, $x$, and $u$, $u_1 \in \mathbb{R}^n$.

With the help of the vectors $x(T, x)$, $T \in S$, defined in 5.4-h, we now define vectors $\tilde{x}(T, x)$ as follows:

$$\tilde{x}(T, x) := (1 - \alpha \delta^T) x(T, x) + \alpha \delta^T \tilde{x}, \quad T \in S$$  \hspace{1cm} (5.8.3)

where $\alpha > 0$ is chosen in such a manner that $\beta_3 \delta^T \mathcal{G}(x)$ (where $\delta$ being the quantity of 5.4-d), and period $S$ such that:

$$\alpha \delta^T < 1, \quad T \in S.$$

So, for every $T \in S$, $\tilde{x}(T, x)$ is a convex linear combination of $x(T, x)$ and $\tilde{x}$, with coefficients $(1 - \alpha \delta^T)$, $\alpha \delta^T$ resp.

From this observation, from the definition of $\tilde{x}(T, x)$, and from theorem 5.5-b (by putting $z = 0$), we may conclude:

**Property 1.**

For every $F$-feasible solution $x$ of an LP-system (5.4.1):

$(x(o), f, p) \in \mathcal{G} \times \mathcal{H} \times \mathcal{Q}(a)$; $F$-or $D$-directed) the vectors $\tilde{x}(T, x)$, $T \in S$ are $F$-feasible solutions of this LP-system.

From the definition of $\tilde{x}(T, x)$ and from the definition of $x(T, x)$, the following property can be derived.

**Property 2.**

$$x(T, x)_{1/\rho} \in \mathbb{R}^n, \quad T \in S$$

$$\mathbb{E}(T, x)_{1/\rho} \in \mathbb{R}^n$$

Now we shall calculate the differences $<p_x, x^* - \tilde{x}(T, x)>_L$.

For $z = 0$ and $1 < \nu < S$, the expression (5.5.3) of proposition 5.5 can be reduced to:

$$\Delta(L, T, x) := <p_x, x^* - \tilde{x}(T, x)>_L $$

$$\Delta(L, T, x) := <p_x, x^* - \tilde{x}(T, x)>_L $$  \hspace{1cm} (5.8.3)

$$<p_x, x^* - \tilde{x}(T, x)>_L = <(D^T)^{-1} H_1 x^* 1/\rho + H_2 x^* 1/\rho + H_3 x^* 1/\rho + H_4 x^*, x^*>_\nu, \quad L \in S.$$
where $M_1$, $N_2$, and $K_3$ are positive numbers, independent of $x(0)$, $f$ and $p$.

From (5.8.3) and from the definition of the vectors $\bar{x}(T,x)$, one can derive:

$$\Delta(L,T,x) := \langle p_p, x \rangle L - \langle p_p, \bar{x}(T,x) \rangle_L^\omega$$

$$= \langle p_p, x \rangle L - \omega \langle I - \omega \bar{A}^T \rangle \langle p_p, x \rangle L - \omega \langle I - \omega \bar{A}^T \rangle \langle p_p, \bar{x} \rangle_L^\omega$$

$$= \langle I - \omega \bar{A}^T \rangle \Delta(L,T,x) + \omega \langle I - \omega \bar{A}^T \rangle \langle p_p, \bar{x} \rangle_L^\omega$$

$$= \langle I - \omega \bar{A}^T \rangle \Delta(L,T,x) + \omega \langle I - \omega \bar{A}^T \rangle \langle p_p, \bar{x} \rangle_L^\omega$$

$$= \langle p_p, x \rangle L - \langle p_p, \bar{x} \rangle_L^\omega, \quad L \geq \lambda T \geq S.$$ \hspace{1cm} (5.8.4)

Defining $M_4 := \sup_{T,x(0)} \langle A^* \hat{U}(T) \rangle L \langle f, \bar{p} \rangle_L^\omega |T_2| x(0), f \rangle \Omega(h) \Omega(g),$

$T, x(0), f$,

theorem 4.5 implies that

$$\langle p_p, x \rangle L \leq M_4, \quad L \geq S, \quad (5.8.5)$$

for all $P$-feasible solutions $x$ of the $L$-systems (5.4.1; $(x(0), f, p) \Omega(h) \Omega(g) \Omega(q)$; $P$-or $W$-directed). \hspace{1cm} (5.8.5)

From (5.8.4), (5.8.5), and from the fact that $\langle I - \omega \bar{A}^T \rangle = 0, \quad \lambda T \geq \lambda L_1^\omega$ and $p \in P_2^\omega$, we may conclude that positive numbers $M_5$, $M_6$, and $M_7$ exist such that:

**Property 3.**

For all $P$-feasible solutions $x$ of the $L$-systems (5.4.1; $(x(0), f, p) \Omega(h) \Omega(g) \Omega(q)$; $P$-or $D$-directed), the following inequalities hold:

$$\Delta(L,T,x) \leq \langle p_p, x \rangle L - \langle p_p, \bar{x}(T,x) \rangle_L^\omega \leq M_5 \lambda T \geq \lambda L \geq S, \quad (5.8.6)$$

$$= \langle p_p, x \rangle L - \langle p_p, \bar{x}(T,x) \rangle L \geq M_6 \lambda T \geq \lambda L \geq S.$$ \hspace{1cm} (5.8.7)

Now, we shall demonstrate the validity of the following property:
Property 6.

A number \( M_4 > 0 \) exists such that:
all \( P \)-feasible solutions \( x \) as mentioned in property 3, with
\[ 1_{\tilde{x}/\rho}^T \tilde{S}^T y_8, \]
are inferior with respect to \( \tilde{x} \).

To prove the validity of this property, we remark that \( \tilde{x} \) and \( \tilde{u} \) are \( P \) and \( D \)-regular solutions, for every \( LP \)-system (5.4.1): \((x(0),f_p)\in(\mathbb{R}^h \times \mathbb{R}^g) \times (\mathbb{R}^q) \); \( P \)-or \( D \)-directed). Then in a similar manner as theorem 5.2 has been derived, one can conclude that a number \( M_4 \) exists, such that every \( P \)-feasible \( x \) as mentioned in property 3 with
\[ 1_{x}^T \tilde{I}^T T > M_4, \]
is inferior with respect to \( \tilde{x} \). Putting \( M_4 := (1/\rho)^T \tilde{S}^T y_8 \), property 4 follows immediately.

In order to prove the first part of the theorem, we put
\[ \tilde{x} = \frac{1}{\rho} (M_5 \rho^{-1} M_7 y_8) + 1_{\tilde{x}/\rho}^T \tilde{I} \]
\[ \frac{1}{\rho} \tilde{x} = 1_{\tilde{x}/\rho}^T \tilde{I}. \]  \hspace{1cm} (5.8.6)

Now, suppose that \( x \) is a \( P \)-feasible solution of a certain \( LP \)-system (5.4.1): \((x(0),f_p)\in(\mathbb{R}^h \times \mathbb{R}^g) \times (\mathbb{R}^q) \); \( P \)-or \( D \)-directed) satisfying (5.8.1) for some \( T_{\geq 1} \). We distinguish two cases:

If \( 1_{x/\rho}^T \tilde{S}^T y_8 \), then property 4 implies that \( x \) is inferior with respect to \( \tilde{x} \), which is a \( P \)-feasible solution of the \( LP \)-system under consideration, and for which (def. 5.8.6):
\[ \tilde{x} \leq \tilde{I} \]

Hence, for this \( P \)-feasible \( x \) the theorem has been proven.

If \( 1_{x/\rho}^T \tilde{S}^T y_8 \), then define
\[ T^* := \min_{T \geq 1} \left\{ \frac{1}{\rho} \right\} \]
\[ \tilde{x} = \frac{1}{\rho} (M_5 \rho^{-1} M_7 y_8) + \tilde{x}. \]  \hspace{1cm} (5.8.7)
Since \( \frac{1}{1-xe^{1}} \leq x \leq \frac{1}{1-xe^{0}} \) the relations (5.8.1), (5.8.6), and (5.8.7) imply that \( 1 > x \) and that \( 1 > x(1-x) \) for \( 0 < x < 1 \). From (5.8.7) and from property 3, we conclude that an E exists such that

\[
< \sum_{\mathbf{p} \in \mathbf{P}} \sum_{\mathbf{q} \in \mathbf{Q}} \mathbf{e} \mathbf{q} (1-x) \mathbf{e}, \quad L > \gamma.
\]  

(5.8.8)

From (5.8.6), (5.8.7), and from property 2, we may conclude:

\[
\prod_{\mathbf{p} \in \mathbf{P}} \prod_{\mathbf{q} \in \mathbf{Q}} \mathbf{e} (1-x) \mathbf{e}, \quad L = \gamma.
\]

(5.8.9)

Finally, property 1 implies that \( \mathbf{x}(1-x) \) is a \( \mathbf{P} \)-feasible solution for the LP-system under consideration. Thus, from (5.8.8) and (5.8.9) we may conclude that for this \( \mathbf{P} \)-feasible \( \mathbf{x} \), too, the theorem is proven.

The second part of the theorem follows from the first part and from the symmetry between the primal and dual systems.
6. OPTIMALITY.

6.1 Introduction.

In this chapter we consider the LP-problem (P- or D-directed; P- and D-regular; \(c^T < 1\)). In that case the theorems 5.2 and 5.3 imply that P-feasible solutions \((x,y)\) and D-feasible solutions \((u,v)\) such that \(x_P \not\in 1^n_+, y_P \not\in 1^n_+\) and \(u_D \not\in 1^n_+, v_D \not\in 1^n_+\), cannot be optimal. Therefore, we may restrict ourselves to feasible solutions \((x,y),(u,v)\) for which

\[
x_P \in 1^n_+, y_P \in 1^n_+,
\]

\[
u_D \in 1^n_+, \nu_D \in 1^n_+.
\]

Hence, the LP-problem (P- or D-directed; P- and D-regular; \(c^T < 1\)) can be formulated as follows:

\[
\begin{align*}
\bar{\beta} &= \sup_{x,y} \langle p, x^\infty \rangle \\(8x(1) + y(1) &= \rho p^\infty(1) \\
\bar{\gamma} &= \sup_{x,y} \langle x(t+1) - Ax(t) + y(t+1) - \rho x^\infty(t+1), t \geq 1 \rangle \\
x_P \in 1^n_+, y_P \in 1^n_+ \\
(6.1.1)
\end{align*}
\]

\[
\bar{\psi} &= \inf_{u,v} \langle e^D, u^\infty \rangle \\
\bar{\psi} &= \inf_{u,v} \langle e^D, v^\infty \rangle \\
u_D \in 1^n_+, \nu_D \in 1^n_+ \\
(6.1.1)
\]

Now, a P-feasible \(x\) is called optimal if \(\langle p, x^\infty \rangle = \bar{\beta}\), and a D-feasible \(u\) is called optimal if \(\langle e^D, u^\infty \rangle = \bar{\psi}\).

The most relevant properties with respect to optimal solutions of this LP-problem are formulated in the last two theorems of this chapter.
6.2 Statement of the linear programming problem.

For every scalar \( a > 0 \) we define a matrix \( G_a \) by:

\[
G_a := \begin{bmatrix}
B & 0 & 0 & \ldots \\
-aA & B & 0 & \ldots \\
0 & -aA & B & \ldots \\
0 & 0 & \vdots & \\
\vdots & \vdots & \ddots & \ddots \\
\end{bmatrix}
\]  \hspace{1cm} (6.2.1)

With the help of these matrices, the LP-problem (6.1.1) can be formulated as follows:

\[
\begin{align*}
\phi_1 &= \sup_{x,y} \langle p, x \rangle, \\
& \text{subject to } G_1 x + y = f_0 \\
& \quad (x, y) \in \mathbb{R}^m \times \mathbb{R}^n.
\end{align*}
\]  \hspace{1cm} (6.2.2)

\[
\begin{align*}
\psi &= \inf_{u,v} \langle f_1, u \rangle, \\
& \text{subject to } G_1 u - v = p, \\
& \quad (u, v) \in \mathbb{R}^m \times \mathbb{R}^n.
\end{align*}
\]

First we shall investigate a more general linear programming problem in the \( l_1 \)-space. The results of this investigation will be transferred later to LP-problem (6.2.2).

6.3 Definition.

We define the following linear programming problem:

\[
\begin{align*}
\phi &= \sup_{x,y} \langle q, x \rangle, \\
& \text{subject to } C x + y = g, \\
& \quad (x, y) \in \mathbb{R}^m \times \mathbb{R}^n.
\end{align*}
\]  \hspace{1cm} (6.3.1)

where:

a) \( q \in l_\infty \) and \( g \in l_1 \)

b) \( C \) is a matrix, generating the bounded linear operator \( G: l_1 \rightarrow l_1 \). The adjoint operator is generated by \( G' \),
so that, for all vectors \( x \in 1_1, u^* \in 1_m \):

\[
\langle x, G'u^* \rangle_m = \langle u^*, Gx \rangle_m.
\] (6.3.2)

We observe that \( \langle q, \cdot \rangle_m \) is a bounded linear functional on \( 1_1 \).

\((x,y) \in 1_1 \times 1_1 \) is called a feasible solution of (6.3.1), if \( x,y \in 1_{1+} \) and \( Gx+y = z \).

\((z,g) \in 1_1 \times 1_1 \) is called an optimal solution of (6.3.1), if \((z,g)\) is a feasible solution of (6.3.1) for which \( \bar{z} = \langle q, x^* \rangle_m \) (\( \bar{z} \) being the supremum appearing in (6.3.1)).

With respect to the analysis of problem (6.3.1), we remark that the so-called generalized Kuhn-Tucker theorem (6.245) is not applicable. This is due to the fact that the interior of \( 1_{1+} \) is empty. For this reason we follow the treatment of Van Slyke and Wets (10), where, with the help of set

\[
\Gamma := \left\{ (\phi, z) \in \mathbb{R}^1 \times 1_1 \mid \phi \leq \langle q, x^* \rangle_m, \ z = Gx+y = z \right\}, \quad (6.3.3)
\]

the following programming problem is joined to (6.3.1):

\[
\sup \phi \mid (\phi, z) \in \Gamma \cap (\mathbb{R}^1 \times \{0\}). \quad (6.3.4)
\]

Clearly, set \( \Gamma \) possesses the following properties (see Fig. 1):

c) \( \Gamma \) is convex,

d) for every \( z_1, z_2 \in 1_1 \), such that \( z_1 \geq z_2 \):

\[
\{ \phi \mid (\phi, z_2) \in \Gamma \} \subset \{ \phi \mid (\phi, z_1) \in \Gamma \},
\]
e) \( \mathbb{R}^1 \times \{0\} \) is closed.

A point \((\phi, z) \in (\mathbb{R}^1 \times 1_1)\) is called a feasible solution of (6.3.4) if \((\phi, z) \in \Gamma \cap (\mathbb{R}^1 \times \{0\})\) and an optimal solution if, in addition, \( \phi \) is equal to the supremum in (6.3.4).
Clearly, the definitions of the problems (6.3.1) and (6.3.4) imply the following proposition:

**6.4 Proposition.**

a) Problem (6.3.1) possesses a feasible solution, if and only if \( U \cap (K^1 \times \{0\}) \neq \emptyset \).
b) The supremum in (6.3.1) is equal to the supremum in (6.3.4).
c) Problem (6.3.1) possesses an optimal solution, if and only if problem (6.3.4) possesses an optimal solution.
d) Problem (6.3.4) possesses an optimal solution, if and only if the supremum in (6.3.4) is bounded and moreover the set \( T \cap (K^1 \times \{0\}) \) is non-empty and closed.

We see that it is sensible first to analyze the joined problem (6.3.4). In that analysis the concept of dual space, now to be introduced, takes a central place.

**6.5 Dual spaces**

The set of bounded linear functionals \( f(x) \) on a Banach space \( X \) can, by introducing the vector sum and scalar multiplication, be taken as a vector space. If to this vector space the following norm is joined:

\[
\|f(x)\|_{X^*} = \sup_{x \in X} |f(x)| \quad |x| \leq 1,
\]

(6.5.1)

where \( |x| \) is the norm of the Banach space \( X \) under consideration, then this new vector space is called the normed dual space of \( X \) or, briefly, the dual space of \( X \). The common notation for this space is \( X^* \). Now, we wish to mention some properties of dual spaces.

(*) For a more detailed treatment see for instance Luenberger(5).
Every bounded linear functional $f(x)$ on the $l_1$-space can be represented uniquely by a vector $v \in l_\infty$ in the following manner:

$$f(x) = \langle v, x \rangle_\infty := \sum_{i=1}^\infty v_i x_i .$$

(6.5.2)

The norm of $l_\infty$ is exactly the $l_\infty$-norm. So, the $l_\infty$-space may be taken as the dual space of $l_1$.

The $c_0$-space is defined as the set of sequences of numbers in $\mathbb{R}$ converging to zero. This space is equipped with the $l_\infty$-norm. Thus, $c_0$ is a subspace of $l_\infty$. In a similar manner as explained for $l_1^*$, the $l_1$-space may be taken as $c_0^*$.

The dual space of $l_\infty$ is not $l_1$. However, every $v \in l_1$ represents a bounded linear functional on $l_\infty$ by $\langle v, x \rangle_\infty$.

Now we shall introduce the concepts weak* convergence, weak* compactness, and weak* closedness, which are all strongly related to the concept of dual space.

Let $X^*$ be the dual space of a Banach space $X$, then we say that a sequence $(f_i)_{i=1}^\infty \subset X^*$ converges weak* to $f_0 \in X^*$ if for every $x \in X$:

$$f_i(x) \to f_0(x) , \quad i \to \infty .$$

(6.5.3)

In this study we shall denote weak* convergence of a sequence $(f_i)_{i=1}^\infty \subset X^*$ to $f_0$, by

$$f_i \overset{\text{w*}}{\rightarrow} f_0, \quad i \to \infty .$$

(6.5.4)

Since $c_0^* = l_1^*$ and $l_1^* = l_\infty^*$, weak* convergence (6.5.4) of a sequence $(f_i)_{i=1}^\infty$ in $l_1^*$ or $l_\infty^*$ implies

$$\langle f_i, x \rangle_\infty \to \langle f_0, x \rangle_\infty , \quad i \to \infty ,$$

(6.5.5)

for every $x \in c_0$ or $x \in l_\infty$, resp.

The concepts of convergence and weak* convergence are further related by:
convergence implies weak$^*$ convergence.

A set $Z \subseteq X^*$ is called weak$^*$ compact, when every sequence
$(f_j)$ in $Z$ contains a subsequence $(f_{j_k})$ which converges
weak$^*$ to a vector $f_0 \in Z$.

A set $Z \subseteq X^*$ is called weak$^*$ closed, when every weak$^*$ conver-
gent sequence $(f_j)$ in $X^*$ converges weak$^*$ to a point in $Z$.

Further, we remark that $l_1^*$ and $l_\infty^*$ are both weak$^*$ closed,
and so, since convergence implies weak$^*$ convergence, closed
as well.

6.6 Definition.

To (6.3.4), we join the following problem:

\begin{align*}
&\text{in } \psi \quad (\omega, u^*) \in (\mathbb{R}^1 \times l_\infty) \tag{6.6.1} \\
&\psi, \nu \quad <\omega, z^*_{\omega} - \theta, \nu > \geq 0, \text{ for all } (\omega, \nu) \in \Gamma.
\end{align*}

Since $(\mathbb{R}^1 \times l_1)^* = (\mathbb{R}^1 \times l_\infty)$, for every $(\omega, u^*) \in (\mathbb{R}^1 \times l_\infty)$ and
\( \psi \in \mathbb{R}^1 \), the expression

\begin{align*}
\tau^* z^* - u^*, z^*_{\omega} - \psi_{\nu} = 0 \tag{6.6.2}
\end{align*}

may be interpreted as a closed hyperplane in $(\mathbb{R}^1 \times l_1^*)$.

Figure 2 gives such a hyperplane, in case $\tau^* = 1$ and
\( (\psi, u^*) \) satisfies the inequality of (6.6.1) for all
\( (\omega, \nu) \in \Gamma \).

Hence, problem (6.6.1) may be considered as a process of seek-
ing a supporting hyperplane (6.6.2)
such that
- \( n^* = 1 \) (i.e. non-vertical),
- the vertical axis is intersected at a point as low as possible.

We introduce the following terms:
- \( (\tilde{\psi}, u^*) \in (\mathbb{R}^1 \times 1_{\text{m}}) \) is called a feasible solution of (6.6.1), if \( (\tilde{\psi}, u) \) satisfies the inequality of (6.6.1) for all \( (\tilde{\psi}, u) \in \Gamma \).
- \( (\tilde{\psi}, u^*) \in (\mathbb{R}^1 \times 1_{\text{m}}) \) is called an optimal solution of (6.6.1), if \( (\tilde{\psi}, u^*) \) is feasible and \( \tilde{\psi} \) is equal to the infimum in (6.6.1).

The geometric interpretation of (6.6.1) suggests that the supremum in (6.3.4) cannot be higher than the infimum in (6.6.1) and that, generally, the supremum in (6.3.4) will be equal to the infimum in (6.6.1). The next two propositions will affirm these presumptions.

6.7 Proposition.
If the problem (6.3.4) and (6.6.1) both possess a feasible solution, then the infimum in (6.6.1) is not smaller than the supremum in (6.3.4). Moreover, in that case the infimum of (6.6.1) and the supremum of (6.3.4) are both finite.

Proof.
The definitions of (6.3.4) and (6.6.1) imply
\[
\langle u^*, \hat{z} \rangle + \tilde{\psi} \geq \phi,
\] (6.7.1)
for all feasible solutions \( (\tilde{\psi}, u) \) and \( (\tilde{\psi}, u^*) \) of (6.3.4) and (6.6.1) resp. Putting \( \hat{z} = 0 \), we have \( \tilde{\psi} \geq \phi \) for all feasible \( (\tilde{\psi}, u) \) and \( (\tilde{\psi}, u^*) \).
The second part of the proposition immediately follows from (6.7.1).
6.8 Proposition.

If the problems (6.3.4) and (6.6.1) both possess a feasible solution, and if

\[ \bar{\Gamma} \cap (\mathbb{R}^4 \times \{0\}) = \bar{\Gamma} \cap (\mathbb{R}^4 \times \{0\}), \]  

(6.8.1)

then the supremum in (6.3.4) is equal to the infimum in (6.6.1).

Proof.

Defining \( \hat{\phi} \) as the supremum in (6.3.4), definition (6.3.6) and supposition (6.8.1) imply

\[ \{ \phi \in \mathbb{R}^4 \mid \phi \leq \hat{\phi} \times \{0\} = \bar{\Gamma} \cap (\mathbb{R}^4 \times \{0\}) = \bar{\Gamma} \cap (\mathbb{R}^4 \times \{0\}) \}. \]

(6.8.2)

Since \( \hat{\phi} \) is finite (proposition 6.7), for every \( \varepsilon > 0 \):

\[ \hat{\phi} - \varepsilon, 0 \notin \bar{\Gamma} \]

(6.8.3)

Since \( \bar{\Gamma} \) is a closed convex (6.3-c) set in \( (\mathbb{R}^4 \times \{1\}) \), it follows from (6.4.3) that, for every \( \varepsilon > 0 \), a closed halfspace

\[ \bar{\Gamma}_c \subset (\mathbb{R}^4 \times \{1\}) \]  

exists (3.134) for which:

\[ \bar{\Gamma} \subset \bar{\Gamma}_c \]

(6.8.4)

Since \( (\mathbb{R}^4 \times \{1\})^\ast = (\mathbb{R}^4 \times \{1\}) \), every halfspace \( \bar{\Gamma}_c \) can be expressed by

\[ \bar{\Gamma}_c = \{ (\bar{\phi}, \bar{z}) \in \mathbb{R}^4 \times \{1\} \mid \eta_c^* \bar{\phi} + \langle u_c^*, \bar{z} \rangle + \psi_c \geq 0 \} \]

(6.8.5)

where \( (\eta_c^*, u_c^*) \in (\mathbb{R}^4 \times \{1\})^\ast \) and \( \psi_c \in \mathbb{R}^4 \), further to be determined.

From (6.8.4) and (6.8.3) we may conclude that \( \eta_c^* < 0 \); for if \( \eta_c^* \geq 0 \), then (6.8.3) implies that not simultaneously \( \hat{\phi}, 0 \in \bar{\Gamma}_c \) and \( (\hat{\phi}, 0) \notin \bar{\Gamma}_c \); however, this is impossible on account of (6.8.4).
Since \( \eta_{\varepsilon}^* < 0 \) and since the expression \( \eta_{\varepsilon}^* \langle u_{\varepsilon}^*, z^\varepsilon \rangle \psi_{\varepsilon} \) is homogeneous in \( \eta_{\varepsilon}^* \), \( u_{\varepsilon}^* \) and \( \psi_{\varepsilon} \), we may choose these quantities in such a manner that \( \eta_{\varepsilon}^* = -1 \). Thus, we may conclude: for every \( \varepsilon > 0 \), a \( \psi_{\varepsilon} \) \( u_{\varepsilon}^* \) \( (R^1 \times 1_{\omega}) \) exists, such that the set

\[
\beta_{\varepsilon} = \{(\phi, \psi) \in R^1 \times 1_{\omega} | \langle u_{\varepsilon}^*, x^\varepsilon \rangle - \phi \psi_{\varepsilon} \geq 0 \}
\]

(6.8.6)
satisfies (6.8.6). This implies, for every \( \varepsilon > 0 \), the existence of a \( (\psi_{\varepsilon}, u_{\varepsilon}^*) \in (R^1 \times 1_{\omega}) \) such that:

\[
\langle u_{\varepsilon}^*, x^\varepsilon \rangle - \phi \psi_{\varepsilon} \geq 0, \text{ for all } (\phi, \psi) \in \beta_{\varepsilon}
\]

(6.8.7)

This implies \( \psi_{\varepsilon} \to \psi_{\varepsilon}^* \), \( \varepsilon \to 0 \), and thus the equality of the supremum in (6.3.4) and the infimum in (6.3.1).

6.9 Example.

We shall illustrate the meaning of condition (6.8.1) with the help of the following programming problem:

\[
\begin{align*}
\sup_{i=1}^n \ x_i \\
\sum_{i=1}^n x_i &\leq 1 + z_1 \\
\sum_{i=1}^n (\frac{1}{i}) x_i &\leq 0 + z_2 \\
x_i &\geq 0, \ i = 1, 2, \ldots
\end{align*}
\]

(6.9.1)

This example can be taken as a particular case of problem (6.3.1).

Putting \( (z_1, z_2) = (0, \varepsilon) \), it appears:
- there is no feasible solution for \( \varepsilon < 0 \),
- for \( \varepsilon = 0 \); \( x_1 = 0 \), i.e. \( 1 \) is the only feasible solution.
so the supremum in (6.9.1) is zero.
- for \( \varepsilon > 0 \), the supremum in (6.9.1) is one.

Figure 3 gives a sketch of the set
\[ \Gamma_i = \{ (x, y) \in \mathbb{R}^2 \mid y_i = 0 \}. \]

Obviously, for this problem:
\[ \Gamma \cap (\mathbb{R}^1 \times \{0\}) \neq \emptyset \cap (\mathbb{R}^1 \times \{0\}). \]

One may deduce that, for \((x_1, x_2) = (0, 0)\), the corresponding problem (6.6.1) has an optimal solution \((u^*, v^*) = (1, 1, 1)\).
Thus, the supremum in (6.9.1) for \((x_1, x_2) = (0, 0)\) is strictly smaller than the infimum of the corresponding problem (6.6.1). This property is known as the so-called "duality gap".

6.10 Definition.
We define the linear programming problem:

\[
\begin{align*}
\omega & = \inf \left\{ \langle g, u^* \rangle \right\}_{u^*, v^*} \quad \text{subject to} \quad C^t u^* - v^* = q \\
& \quad u^*, v^* \in 1_m
\end{align*}
\] (6.10.1)

where \( g \in 1, q \in 1_m \) and \( C \) are the same quantities as introduced for problem (6.3.1).

We observe that this problem is formulated in \( 1_m \), which is the dual space of the space in which problem (6.3.1) is formulated. The nomenclature with respect to the concept of duality as introduced in 52.5, is based on this consideration, and on the relations between (6.3.1) and (6.10.1), further to be deduced.

First we shall give some relations between the problems (6.6.1) and (6.10.1).

6.11 Proposition.
\((u^*, v^*) \in (\mathbb{R}^1 \times 1_m)\) is a feasible solution of (6.6.1), if and only
if \((\Phi, u^*)\) possesses the following properties:

\[
\begin{align*}
\langle g, u^* \rangle &= \Phi \\
 u^* &\in \mathbb{R}_+^{m} \\
v^* &= G^t u^* \in \mathbb{R}_+^{m*}
\end{align*}
\]  
(6.1.1)

Proof.

The definition of problem (6.6.1), the definition (6.3.3) of \(\Gamma\) and supposition 6.3-b imply successively the equivalence of the following statements:

\[
\begin{align*}
\langle \Phi, u^* \rangle &\in (\mathbb{R}^{+} \times \mathbb{R}_+^{m}) \text{ is a feasible solution of (6.6.1),} \\
\langle u^*, z \rangle &\geq 0, \forall (\Phi, z) \in \Gamma, \\
\langle u^*, ax^y \rangle &\geq \langle q, x_y \rangle, \forall x \in \mathbb{R}_+^m, \\
\langle G^t u^* - q, x \rangle &+ \langle u^*, y \rangle - \langle g, u^* \rangle \psi \geq 0, \forall y \in \mathbb{R}_+^m.
\end{align*}
\]  
(6.11.2)

Let \((\Phi, u^*)\) be a feasible solution of (6.6.1), then the necessity of the conditions (6.11.1) can be proved as follows:

- Putting \(x := 0, y := 0\), equality (6.11.2) implies:

\[
\langle g, u^* \rangle = 0
\]

- Putting \(x := 0\), equality (6.11.2) implies:

\[
\langle u^*, y \rangle - \langle g, u^* \rangle \psi \geq 0, \forall y \in \mathbb{R}_+^m
\]  
(6.11.3)

This is possible only when \(u^* \in \mathbb{R}_+^m\); for, \(u^* \not\in \mathbb{R}_+^m\) implies the existence of \(x \in \mathbb{R}_+^m\) such that the left hand side of (6.11.3) is negative.

- Defining \(v^* := G^t u^* - q\) and putting \(y := 0\), equality (6.11.2) implies:

\[
\langle v^*, x \rangle = \langle g, u^* \rangle \psi \geq 0, \forall x \in \mathbb{R}_+^m
\]  
(6.11.4)

This is possible only if \(v^* \in \mathbb{R}_+^m\).
Thus it appears that the conditions (6.11.1) are necessary.

The sufficiency of the conditions (6.11.1) immediately follows from (6.11.2), because (6.11.1) implies:

\[ \begin{align*}
\langle g, u^\ast \rangle_m + \psi & \geq 0 \\
\langle g'w'^\ast, q, x \rangle_m & \geq 0, \text{ for all } x \in l^1_+ \\
\langle u^\ast, y \rangle_m & \geq 0, \text{ for all } y \in l^1_+
\end{align*} \]

and so the validity of (5.11.2) for all \( x, y \in l^1_+ \).

6.12 Corollary.

a) Problem (6.10.1) possesses a feasible solution, if and only if problem (6.6.1) possesses a feasible solution.

b) The infimum in (6.10.1) is equal to the infimum in (6.6.1).

c) Problem (6.10.1) possesses an optimal solution, if and only if problem (6.6.1) possesses an optimal solution.

6.13 Proposition.

If the problems (6.5.1) and (6.10.1) both possess a feasible solution, then:

a) \( \psi \leq \psi' \)

b) For every feasible solution \((x,y),(u,v)\) of (6.3.1),(6.10.1) resp. the following equality holds:

\[ \langle q, x \rangle_m = \langle g, u^\ast \rangle_m - \langle v', x \rangle_m - \langle u^\ast, y \rangle_m \]

c) If the set \( \Gamma \) (def 6.3.3) satisfies

\[ \Gamma \cap (u^1 \times \{0\}) = \Gamma' \cap (u^1 \times \{0\}) \]

then

\[ \psi = \psi' \]

d) If the set \( \Gamma' \) satisfies (6.13.1), then feasible solutions
(x, y), (u, v) of (6.3.1), (6.10.1) resp. are both optimal if and only if

\[ \langle v^*, x \rangle_m - \langle u^*, y \rangle_m = 0. \]

Proof:

(a) This property immediately follows from the propositions 6.4, 6.7 and 6.12.

(b) Let (x, y) and (u, v) be feasible solutions of (6.3.1) and (6.10.1) resp. Then, 6.3-b and the definition of the problems (6.3.1), (6.10.1) imply:

\[ \langle q, x \rangle_m = \langle C'u'' - v'', x \rangle_m = \langle C'u'', x \rangle_m - \langle v'', x \rangle_m = \]

\[ = \langle u'', 0 \rangle_m - \langle v'', x \rangle_m = -\langle u'', g - y \rangle_m - \langle v'', x \rangle_m = \]

\[ = \langle 0, u'' \rangle_m - \langle u'', y \rangle_m - \langle v'', x \rangle_m. \]

(c) The validity of this property follows from the propositions 6.4, 6.7, 6.8 and 6.12.

(d) This property is implied by b) and c).

6.14 Remark.

In the following proposition conditions are given, implying the existence of an optimal solution of (6.3.1) and the validity of the equality

\[ \Gamma \cap (R^1 \times Q) = \Gamma \cap (R^1 \times \{0\}). \]

Later, it will appear that an LP-problem (P- or D-directed; P- and D-regular; \( p < 1 \)) satisfies these conditions.

6.15 Proposition.

If the problems (6.3.1) and (6.10.1) are such that:

a) The conditions 6.3-a,b are satisfied.
b) \( q \neq 0 \).

c) Matrix \( G' \) generates a bounded linear operator \( G : c_0 \to c_0 \).

d) Problem (6.3.1) possesses a feasible solution.

e) Numbers \( M_1, M_2 \) exist such that, for every \( (q, z) \in \Gamma \cap (R^1 \times _1 \Gamma) \), the system

\[
\begin{align*}
Gz & \leq g * z \\
|x_{1}^{1} & \leq M_1 \| z_1 \| \\
<q, x_1^{1} & \geq 0
\end{align*}
\]

(6.15.1)

possesses a solution \( x \in _1 \Gamma \).

Then, problem (6.3.1) possesses an optimal solution, and the equality

\[
\Gamma \cap (R^1 \times \{0\}) = \Gamma \cap (R^1 \times \{0\})
\]

holds.

Proof.

Consider a sequence:

\[
((\phi_1, x_1^{1}))^{m \in \Gamma} \cap (R^1 \times _1 \Gamma)
\]

(6.15.3)

\[
(\phi_1, x_1^{1}) = (\phi_0, z_0), \quad i \to w.
\]

(6.15.4)

The existence of such a sequence is implied by d), for \( \Gamma \cap (R^1 \times \{0\}) \neq \emptyset \) (proposition 6.4-a).

Supposition e) implies the existence of a sequence \((x_1^{1})^{m \in \Gamma} \cap _1 \Gamma \) satisfying

\[
\begin{align*}
Gx_1^{1} & \leq g * z_1 \\
\| x_1^{1} & \leq M_1 \| x_1^{1} \| \\
<q, x_1^{1} & \geq 0
\end{align*}
\]

(6.15.5)
If we define the set
\[
\sigma := \{ x \in L \mid \|x\| \leq M_1 \sup_{i \geq 1} \|z_i\| \},
\]
then (6.15.3) implies
\[
[\{x_i\}]^\infty_1 \subset \sigma \quad (6.15.6)
\]
Since \( \sigma \) is weak* compact (Ascoli's theorem (1.272)), (6.15.6) implies the existence of a subsequence \([x_{i(k)}]_{k=1}^\infty\) of \([x_i]_1^\infty\) which converges weak* to a point \(x_0 \in \sigma\), i.e.,
\[
x_{i(k)} \rightharpoonup x_0, \quad k \to \infty. \quad (6.15.7)
\]
Supposition b) and weak* convergence (6.15.7) imply:
\[
\langle q, x_{i(k)} \rangle_{L^2} \to \langle q, x_0 \rangle_{L^2}, \quad k \to \infty. \quad (6.15.8)
\]
The relations (6.15.4), (6.15.5), and (6.15.8) imply:
\[
\langle q, x_0 \rangle_{L^2} \geq \Phi_0. \quad (6.15.9)
\]
The suppositions a) and c) imply for every \(r \in c_0\):
\[
\begin{align*}
0^*r & \in c_0, \\
\langle r, G x_i \rangle_{L^2} & = \langle r, G x_{i}^* \rangle_{L^2}, \quad i \geq 0
\end{align*}
\]
and so, in connection with (6.15.7):
\[
\langle r, G x_{i(k)} \rangle_{L^2} = \langle r, G x_0 \rangle_{L^2}, \quad k \to \infty, \text{ for all } r \in c_0. \quad (6.15.10)
\]
From (6.15.4), (6.15.5), and (6.15.10), we may conclude:
\[
G x_0 \leq g^* x_0. \quad (6.15.11)
\]
Since \( L^1 \) is weak* closed, (6.15.3), (6.15.4), (6.15.7), and 
\[ \{x_i(y)\}_{x^i} \in L^1 \] imply
\[ z_{x^o} \in L^1. \]  
(6.15.12)

The definition (6.3.2) of \( \Gamma \) and the relations (6.15.9), (6.15.11), (6.15.12) imply \( (y_{x^o}, z_{x^o}) \in \Gamma \cap (L^1 \times L^1). \) Thus, we find that every convergent sequence \( \{f_{x^i}, A_{x^i}\}_{x^i} \cap \Gamma \cap (L^1 \times L^1) \) converges to a point in \( \Gamma \cap (L^1 \times L^1). \) Hence:
\[ \Gamma \cap (L^1 \times L^1) = \Gamma \cap (L^1 \times L^1). \]  
(6.15.13)

With the help of this result the proof will be completed as follows.

Since the set \( (L^1 \times \{0\}) \) is closed, (6.15.13) implies:
\[ \Gamma \cap (L^1 \times \{0\}) = \Gamma \cap (L^1 \times \{0\}) \]  
(6.15.14)

Supposition e) implies the boundness of the supremum in (6.3.4), and so, by virtue of (6.15.14) and proposition 6.4, we may conclude: problem (6.3.1) possesses an optimal solution.

The validity of (6.15.2) may be proved as follows.

Equality \( \Gamma = (\Gamma \cap (L^1 \times L^1)) \cup (\Gamma \cap (L^1 \times L^1)) \) implies successively:
\[ \Gamma = (\Gamma \cap (L^1 \times L^1)) \cup (\Gamma \cap (L^1 \times L^1)), \]
\[ \Gamma \cap (L^1 \times \{0\}) = (\Gamma \cap (L^1 \times L^1)) \cap (L^1 \times \{0\}) \cup (\Gamma \cap (L^1 \times L^1)) \cap (L^1 \times \{0\}), \]  
(6.15.15)

Property 6.3-e implies:
\[ (\Gamma \cap (L^1 \times L^1)) \cap (L^1 \times \{0\}) \subset (\Gamma \cap (L^1 \times L^1)) \cap (L^1 \times \{0\}) \]  
(6.15.16)
With the help of (6.15.13), (6.15.16), (6.15.13), and (6.15.14), we derive:

\[
\Gamma \cap (\mathbb{R}^{l_x} \times \{0\}) = (\Gamma \cap (\mathbb{R}^{l_x} \times \{0\})) \cup (\mathbb{R}^{l_x} \times \{0\}) =
\]

\[
\Gamma \cap (\mathbb{R}^{l_x} \times \{0\}) = \Gamma \cap (\mathbb{R}^{l_x} \times \{0\}) .
\]

Thus we find:

\[
\Gamma \cap (\mathbb{R}^{l_x} \times \{0\}) = \Gamma \cap (\mathbb{R}^{l_x} \times \{0\}) .
\]

6.16 Remark.

By virtue of the propositions 6.13 and 6.14, one may conclude:

- Problem (6.3.1) possesses an optimal solution.
- The supremum in (6.3.1) is equal to the infimum in (6.10.1).

We remark that no statement is included with respect to the existence of an optimal solution of problem (6.10.1).

By virtue of the relations between \( l_1 \), \( l_1^2 \), and \( l_1^1 \), as described in §2.2, the properties with respect to the problems (6.3.1) and (6.10.1) are applicable to our original LP-problem (P- or D-directed; P- and D-regular; \( \beta \neq 1 \)) as formulated in §6.1. To that end, we transform the LP-problem with the help of a coefficient \( \beta \in [1, \frac{1}{10}] \), which is chosen in such a manner that the properties 5.7-a,b of proposition 5.6 are valid.

Hence, in the next theorem, we shall consider the following LP-problem:

\[
\tilde{\eta} := \sup_{x \in \mathbb{R}^{l_x}, y \in \mathbb{R}^{l_y}} \left\{ G_{xy}^{\beta} x - f_{\beta} \right\} \quad \text{subject to} \quad x \in \mathbb{R}^{l_x}, y \in \mathbb{R}^{l_y}, \quad (6.16.1)
\]

\[
\tilde{\nu} := \inf_{u^* \in \mathbb{R}^{l_u}, v^* \in \mathbb{R}^{l_v}} \left\{ G_{%u^*}^{\beta} u^* - f_{\beta} \right\} \quad \text{subject to} \quad u^* \in \mathbb{R}^{l_u}, v^* \in \mathbb{R}^{l_v}, \quad (6.16.2)
\]
where, (6.16.1) is the $\phi$-transformed primal problem (6.1.1) and (6.16.2) the $(1/\phi \psi)$-transformed dual problem (6.1.1).

We remark that $\psi \in \mathbb{L}_{1/m^2}$, $\psi \in \mathbb{L}_m$, and $\xi^0 \in \mathbb{L}^m_0$ imply:

$\psi \in \mathbb{L}_m$ and $\xi^0 \in \mathbb{L}^m_0$.

The next two properties will show that the matrix $G_\alpha$ for every $\alpha > 0$ satisfies the conditions 6.3-b and 6.15-c.

4.17 Proposition.

Matrices $G_\alpha$ and $G'_\alpha$ (def 6.2.2) generate the following linear operators:

\[
G_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0, \quad G'_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0, \quad G_0 : \mathbb{C}^N_0 \rightarrow \mathbb{C}^N_0, \quad G'_0 : \mathbb{C}^N_0 \rightarrow \mathbb{C}^N_0, \quad (6.17.1)
\]

\[
G_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0, \quad G'_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0, \quad G_0 : \mathbb{C}^N_0 \rightarrow \mathbb{C}^N_0, \quad G'_0 : \mathbb{C}^N_0 \rightarrow \mathbb{C}^N_0, \quad (6.17.2)
\]

which are all bounded.

**Proof.**

Defining

\[
N_\alpha := \prod_{i=1}^{N} \prod_{j=1}^{\tau} (|a_{ij}| + |b_{ij}|), \quad (6.17.3)
\]

one can derive:

\[
|G_\alpha x|_m \leq N_\alpha \|x\|_m, \quad \text{for every } \tau > 1, \ x \in \mathbb{L}^m_0.
\]

So, for all $x \in \mathbb{L}^m_0$ we have:

\[
G_\alpha x \in \mathbb{L}^m_0, \quad |G_\alpha x|_m \leq N_\alpha \|x\|_m. \quad (6.17.4)
\]

Clearly, matrix $G_\alpha$ defines the bounded linear operator

$G_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0$.

In a similar manner, it can be proved that matrix $G'_\alpha$ defines a bounded linear operator $G'_\alpha : \mathbb{L}^m_0 \rightarrow \mathbb{L}^m_0$. 

\[ - 102 - \]
Definition (6.17.3) and definition (6.2.1) imply:

\[ \|G_w^T\|_{\infty} \leq N_0 \|w\|_{\infty}^{T-1}, \]

for all \( T > 1 \), \( w \in c_0^N \), and so for all \( x \in c_0^N \):

\[ G_x \in c_0^N. \tag{6.17.5} \]

From (6.17.5) and (6.7.4) we may conclude: matrix \( G_\alpha \) generates a bounded linear operator \( G_\alpha : c_0^N \to c_0^M \).

The statement with respect to the linear operators (6.17.2) may be proved in a similar manner.

6.18 Proposition.

For every \( x \in l_1^N, u^* \in l_\infty^M \):

\[ \langle x, G'u^* \rangle = \langle u^*, G_x \rangle. \tag{6.18.1} \]

For every \( u \in l_\infty^M, x^* \in l_1^N \):

\[ \langle u, G_x x^* \rangle = \langle x^*, G'u \rangle. \tag{6.18.2} \]

Proof.

From the definition (6.2.1) of \( G_\alpha \), one can derive:

\[ \langle x, G'u^* \rangle = \langle u^*, G_x \rangle + \langle u^*, (T+1)'Ax(T) \rangle, \tag{6.18.3} \]

for every \( x \in l_1^N, u^* \in l_\infty^M \), and every \( T \geq 1 \).

Since \( x \in l_1^N \) and \( u^* \in l_\infty^M \), we may conclude successively:

\[ (Ax(t)) \to 0, \ t \to \infty, \tag{6.18.4} \]

\[ u^*(t+1)'Ax(t) \to 0, \ t \to \infty. \]

The relations (6.18.3) and (6.18.4) imply:
\langle x, G, u^* \rangle_{m} = \langle u^*, G, x \rangle_{m},

for all \( x \in l^m_1, u^* \in l^m_1 \).

Equality (6.18.2) may be derived in a similar manner.

6.19 Theorem.

For an LP-problem (\( P \) or \( D \)-directed; \( P \)- and \( D \)-regular; \( P > 1 \)), the following properties hold:

a) The supremum in the primal problem is equal to the infimum in the dual problem.

b) The primal and dual problems both possess an optimal solution.

c) Numbers \( \beta \in [1, 1/\mu^1 \}, \mu_1 > 0 \), and \( \mu_2 > 0 \) exist such that for every \( P \)-optimal \( x \) and every \( D \)-optimal \( u \):

\[
x_0^m \in l^m_1, \quad l^m_1 \leq \mu_1
\]

\[
u_0^m \in l^m_1, \quad l^m_1 \leq \mu_2
\]

(6.19.1)

(6.19.2)

d) A feasible solution \((x, y), (u, v))\) is optimal, if and only if simultaneously

\[
\langle v, x \rangle + \langle u, y \rangle = 0, \quad T \geq 1
\]

\[
u(T^1)^* A(x^1) > 0, \quad T \to \infty
\]

(6.19.3)

(6.19.4)

Proof.

Since the LP-problem is \( P \)- or \( D \)-directed and \( P \)- and \( D \)-regular, and since \( P < 1 \), one can derive from proposition 5.6 that numbers \( \beta \in [1, 1/\mu^1 \}, \mu_1 > 0 \) and \( \mu_2 > 0 \) exist for which the following property holds:

Property 1: for every \( x \in l^m_1, u \in l^m_1 \) satisfying
a vector $\bar{x} \in \mathbb{R}^n_+$ exists such that

$$
\begin{aligned}
G_{G_0} & \leq f_{G_0}^* x \\
1 & \leq N_1 x_1
\end{aligned}
$$

Since $p_1/B \in c^n$ and $f_{G_0}^* \in \mathbb{R}^n_+$, we may define set $\Gamma$ in a similar way as done in (6.3.3), i.e.,

$$
\Gamma := \left\{ (\phi, z) \in (\mathbb{R}^n_+ \times \mathbb{R}^n_+) \left| \begin{array}{l}
\phi \leq f_{p_1/B}^* x \\
z = G_{G_0} x + y - f_{G_0}^* x, \quad x \in \mathbb{R}^n_+, y \in \mathbb{R}^n_+
\end{array} \right. \right\}
$$

(6.19.5)

Property 1 and definition (6.19.5) imply:

Property 2: for every $(\phi, z) \in \Gamma \cap (\mathbb{R}^n_+ \times \mathbb{R}^n_+)$, the system

$$
\begin{aligned}
G_{G_0} & \leq f_{G_0}^* x \\
1 & \leq N_1 x_1
\end{aligned}
$$

possesses a solution $x \in \mathbb{R}^n_+$.

Since $p_1/B \in c^n$ and $f_{G_0}^* \in \mathbb{R}^n_+$, we may conclude by virtue of the propositions 6.17, 6.18, and of property 2, that the LP-problems (6.6.1) and (6.6.2) satisfy the conditions of proposition 6.13 and 6.15. Hence, we have:
Property 2: the supremum \( \hat{\psi} \) in (6.16.1) is equal to the infimum \( \check{\psi} \) in (6.16.2), and problem (6.6.1) possesses an optimal solution.

With the help of this result, it will be shown that for the original LP-problem (6.2.2):

\[
\hat{\psi} := \sup_{x,y} \langle p, x \rangle_\infty \quad | \quad G_1 x = g_1, x \in L_1^n, y \in L_1^m \quad (6.19.6)
\]

\[
\check{\psi} := \inf_{u,v} \langle s, u \rangle_\infty \quad | \quad G_2 u - v = g_2, u \in L_1^m, v \in L_1^n \quad (6.19.7)
\]

the following properties hold:

4) The supremum \( \hat{\psi} \) in (6.19.6) is equal to the infimum \( \check{\psi} \) in (6.19.7).

5) Problem (6.19.6) possesses an optimal solution.

6) Numbers \( \delta \in \mathbb{R}, \mu_1, H_1 > 0, \) and \( M_2 > 0 \) exist, such that for all optimal solutions \( x \) of (6.19.6) and all optimal solutions \( u \) of (6.19.7):

\[
x_{\delta, u} \in L_1^n, \quad |x_{\delta, u}|_1 \leq H_1
\]
\[
u_{\delta, u} \in L_1^m, \quad |u_{\delta, u}|_1 \leq M_2
\]

Clearly, parts a, b, and c of the theorem are proved.

4) Let \((x,y)\) be a feasible solution of (6.16.1), then \((x/y, y/y)\) is a feasible solution of (6.19.8). This implies:

\[
\hat{\psi} = \check{\psi} \quad (6.19.8)
\]

Let \((u,v)\) be a feasible solution of (6.16.2), then \((u_{\delta, \mu}, v_{\delta, \mu})\) is a feasible solution of (6.19.7). This implies:

\[
\check{\psi} \leq \hat{\psi} \quad (6.19.9)
\]
Since \( \hat{\psi} \leq \varphi \) (Theorem 4.5) and \( \hat{\psi} = \hat{\varphi} \) (property 3), the inequalities (6.19.8) and (6.19.9) imply \( \hat{\psi} \leq \varphi = \hat{\psi} = \hat{\varphi} \).

(5) Since \( \hat{\psi} = \hat{\varphi} \), the existence of an optimal solution in (6.16.1) implies the existence of an optimal solution in (6.19.6).

(6) This property follows from (5) and from the symmetry between the primal and dual.

(7) This property can be derived from Theorem 5.7.

To prove part d) of the theorem, we first assume that the LP-problem is D-directed, which implies:

\[
v(t) = A'u(t) \geq 0, \quad t \geq 1,
\]
for all D-feasible solutions \((u,v)\) of (6.2.2).

For all D-feasible solutions \((x,y)\) and D-feasible solutions \((u,v)\) (Proposition 6.2) the following inequalities hold:

\[
\langle p_n, x \rangle_T = \langle \hat{f}_\rho, u \rangle_T - \langle u, y \rangle_T - \langle v, x \rangle_{T-1} - \langle v(t) - u(T+1), x(T) \rangle_T > 0.
\]

(6.19.11)

Now, let \((x,y)\) and \((u,v)\) be optimal, then \(\langle p_n, x \rangle = \langle \hat{f}_\rho, u \rangle\), (6.19.10), (6.19.11), and the non-negativity of \((x,y),(u,v)\) imply the validity of (6.19.3) and (6.19.4). Hence, these conditions are necessary, in case the D-directedness the LP-problem is assumed.

Now, suppose that the feasible solutions \((\hat{x}, \hat{y})\) and \((\hat{u}, \hat{v})\) satisfy (6.19.3) and (6.19.4), then (6.19.11) implies \(\langle p_n, \hat{u} \rangle = \langle \hat{f}_\rho, \hat{u} \rangle\). Since, for all feasible \((x,y)\) and \((u,v)\):

\[
\langle p_n, x \rangle \leq 0 \leq \langle \hat{f}_\rho, u \rangle,
\]
we may conclude that \((\hat{x}, \hat{y})\) and \((\hat{u}, \hat{v})\) are optimal. This proved the sufficiency of the conditions (6.19.3), (6.19.4), in case the D-directedness of LP-problem is assumed.
When we depart from the assumption that the LP-problem is $P$-directed, then inequality:

$$Ax(t) + \eta^t f^0(t+1) \geq 0, \quad t \geq 1$$

may be used. The proof may further be completed in a similar manner.

6.20 Example.

A significant difference between the result derived in the last theorem and the well-known criterion of optimality for linear programming in a finite dimensional space, is constituted by the appearance of the condition

$$u(x^*)'Ax(z) > 0, \quad z = \infty$$

in theorem 6.19. We shall illustrate the meaning of this condition with the help of the following example, where

$$A := \begin{bmatrix} 1 & 0 \\ 0 & 5 \end{bmatrix}, \quad B := \begin{bmatrix} 0 & 0 \\ 0 & 10 \end{bmatrix}, \quad \eta := \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad f := \begin{bmatrix} 0 \\ 3 \end{bmatrix},$$
$$p := 1, \quad n := 0.8, \quad x(0) := \begin{bmatrix} 1 \\ 1 \end{bmatrix}.$$  

The corresponding LP-problem is $P$- and $D$-directed, $P$- and $D$-regular and moreover $p_2 > 1$. So, the conditions of theorem 6.19 are satisfied.

For this problem, one may derive that

$$x(t) = \begin{bmatrix} 1 \\ 1 \end{bmatrix} + \left( 10^{-1} \right)^t \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$
$$y(t) = 0,$$
$$u(t) = (0.9)^t \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$
$$v(t) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad t \geq 1.$$
is an optimal solution, with $\langle x, u \rangle_\infty = \langle f_0, u \rangle_\infty = 4$.

It appears that

$$\hat{u}(t) := (0.8) \begin{bmatrix} 0 \\ 1/6 \end{bmatrix} + (0.9) \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad t \geq 0$$

is a D-feasible solution. For this D-feasible solution we find:

$$\langle x, u \rangle_\infty * \langle y, v \rangle_\infty = 0, \quad T \geq 1,$$

$$\hat{u}(t) \in \mathbb{R}^a, \quad T \geq 1$$

$$\langle f_0, u \rangle_\infty = 8.5.$$  

Although (6.19.2) is satisfied, it appears that $(\hat{u}, \hat{v})$ is not optimal.

6.21 Theorem.

For an LP-problem (P- or D-directed; superregular) the following properties hold:

a) The supremum in the primal problem is equal to the infimum in the dual problem.

b) The primal and dual problems both possess an optimal solution.

c) Positive numbers $M_1$ and $M_2$ exist such that the following is valid:
A feasible solution $(x, y, (u, v))$ is optimal if and only if simultaneously:

$$\|x\|_{\infty}^{1,T} \leq M_1, \quad T \geq 1, \quad (6.21.1)$$

$$\|u\|_{\infty}^{1,T} \leq M_2, \quad T \geq 1, \quad (6.21.2)$$
\[ \langle v, x \rangle^*_T \langle u, y \rangle_T = \gamma, \; T \geq 1. \]  \hspace{1cm} (6.21.3)

**Proof.**

The superregularity implies P- and D-regularity and the inequality $\delta \gamma < 1$, and so, by virtue of theorem 6.19, the validity of a) and b).

Since $\delta \gamma < 1$, the inequalities (6.21.1) and (6.21.2) imply the convergence $u^{(k+1)} = (T^k + A)x \rightarrow 0$, $T \rightarrow 0$, we may conclude by virtue of theorem 6.19 that (6.21.1), (6.21.2), and (6.21.3) are sufficient conditions for the optimality of a feasible solution $((x,y),(u,v))$.

From theorem 5.8, the necessity of the conditions (6.21.1), (6.21.2), and (6.21.3), for the optimality of a feasible solution $((x,y),(u,v))$, immediately follows.
7. PARAMETRIC PROPERTIES

7.1 Introduction.

In this chapter we consider a LP-problem

\[ \phi(t^0, p) := \sup_{(x,y)} \left[ C^o x + y = f^0 \right| \begin{array}{l}
C_i^o x + y = f^0 \\
x \in I^o, y \in I^o
\end{array} \]

\[ \psi(t^0, p) := \inf_{(u,v)} \left[ C^o u - v = p^0 \right| \begin{array}{l}
C_i^o u - v = p^0 \\
u \in I^r, v \in I^r
\end{array} \right], \]

(7.1.1)

for all vectors \( t^0, p \), from sets \( I^o \subset I_m^o, P \subset I_m^o \) further to be described, with the objective to derive some properties with respect to the continuity of \( \phi(t^0, p) \) and of the set of optimal solutions.

The fixed matrices \( A \) and \( B \), which generate \( G_i \), are supposed to be such that a \( f^0 \) or \( p \) exists for which the LP-problem is \( P \)- or \( D \)-directed. With respect to the fixed quantities \( p \) and \( t \) it is supposed that \( pt < l \).

Further, we restrict ourselves to sets \( I^o \subset I_m^o \) and \( P \subset I_m^o \) which satisfy the following conditions:

a) \( f^0 \) and \( P \) are compact.
b) For every \( (t^0, p) \in I^o \times P \) the LP-problem (7.1.1) is superregular.
c) For every \( (t^0, p) \in I^o \times P \) the LP-problem (7.1.1) is \( P \)- or \( D \)-directed.

With respect to the last condition, we remark that the LP-problem is called \( P \)-directed for every \( f^0 \in I^o \), if for every \( f^0 \in I^o \) a \( f \in I^o \) and a \( x(\cdot) \in I^o \) exist such that

\[ (f(1), \ldots, f(2), \ldots, f(\cdot), \ldots) = (f^0(1), f^0(2), \ldots, f^0(\cdot), \ldots) \]

and such that \( f \) satisfies the conditions (2.3) for \( P \)-directedness.
The most important results of this chapter are formulated in the theorems 7.1 and 7.2.

7.2 Definitions.

For the LP-problem and the sets \( P^0 \) and \( P \) as described above, we define the mappings \( X : P^0 \times P \to \mathbb{R}^n \times \mathbb{R}^m \), \( X^0 : P^0 \to \mathbb{R}^n \), \( XY : P^0 \times P \to \mathbb{R}^n \times \mathbb{R}^m \), \( UV : P^0 \times P \to \mathbb{R}^n \times \mathbb{R}^m \) by:

\[
X(f^0, p) := \{ x \in l^\infty_n \mid <p, x> = \phi(f^0, p) \} , \quad (7.2.1)
\]

\[
XY(f^0) := \{ (x, y) \in l^\infty_n \times l^\infty_m \mid G_{x, y} = f^0 \} , \quad (7.2.2)
\]

\[
XY(f^0, p) := XY(f^0) \cap X(f^0, p) \subseteq l^\infty_m , \quad (7.2.3)
\]

\[
UV(f^0, p) := \{ (u, v) \in l^\infty_n \times l^\infty_m \mid G_{u, v} = p \}
\]

\[
<\phi(f^0, p), v> = \psi(f^0, p) , \quad (7.2.4)
\]

So for every \( f^0 \in P^0 \), \( XY(f^0) \) is the set of \( l/p \)-transforms of \( o \)-dominated \( P \)-feasible solutions. If \( P^0 \) and \( P \) satisfy 7.1-a,b,c, then theorem 6.21 and definition (7.2.4) imply that for every \( (f^0, p) \in P^0 \times P \), \( XY(f^0, p) \) is the set of \( l/p \)-transforms of \( P \)-optimal solutions of LP-problem (7.1.1). In a similar manner, we may conclude that \( UV(f^0, p) \) is the set of \( l/p \)-transforms of \( l/p \)-optimal solutions.

Further we wish to introduce two more general concepts.

The graph of a mapping \( D : C_1 \to \mathbb{R}(C_1) \) is the set defined by:

\[
\text{Graph}(C_1; D) := \{ (c, d) \mid c \in C_1, d \in D(c) \} . \quad (7.2.5)
\]

The sphere in \( l^b_\infty \) with a radius \( R \) is defined by:

\( \ast \) The power set of a set \( C \) is denoted by \( \mathcal{P}(C) \).
\[ \sigma^b_m(M) := \{ x \in I_m^b \mid \| x \|_m \leq M \} \]  

(7.2.6)

7.3 Theorem

If the sets \( F^0 \subseteq I_m^0 \) and \( P \subseteq I_m^0 \) satisfy the conditions 7.1-a, b, c, then the following properties hold:

a) For every \( (f^0, p) \in F^0 \times P \):
   - the LP-problem (7.1.1) possesses a \( P \)-optimal solution and a \( P \)-optimal solution,
   - \( \hat{\sigma}^0 \) (def. 7.2.3) is the set of 1/ \( p \)-transforms of \( P \)-optimal solutions,
   - \( \hat{\sigma}^1 \) (def. 7.2.4) is the set of 1/ \( p \)-transforms of \( P \)-optimal solutions.
   - \( \hat{\sigma}(f^0, p) = \hat{\sigma}(f^0, p) \).

b) Numbers \( M_1 \) and \( M_2 \) exist such that
   \[ \hat{\sigma}^0(f^0, p) \subseteq \sigma^0_m(M_1) \times \tau^0_m(M_1) \]  
   \[ \hat{\sigma}^1(f^0, p) \subseteq \sigma^1_m(M_2) \times \tau^1_m(M_2) \]  

c) Numbers \( M_1 \) and \( M_2 \) exist such that for every \( (f^0, p), (f^0, p) \in F^0 \times P \):
   \[ \| \hat{\sigma}(f^0, p) - \hat{\sigma}(f^0, p) \| \leq M_1 \| (f^0 - f^0)_0 \|_{1, \rho} + M_2 \| (P - P)_0 \|_{1, \rho} \]  

Proof.

(a) For every \( (f^0, p) \in F^0 \times P \) the LP-problem (7.1.1) satisfies the conditions of theorem 6.19. From this theorem property a) may be derived.

(b) For every \( (q^0, q) \in F^0 \times P \), the conditions of theorem 5.8 are satisfied. By virtue of this theorem we may conclude that, for every \( (q^0, q) \in F^0 \times P \), neighbourhoods \( \tau(q^0) \subseteq I_m^1 \) and \( \tau(q) \subseteq I_m^1 \) and a number \( M(q^0, q) \) exist such that
   \[ \hat{\sigma}^0(\tau(q^0) \cap F^0, \tau(q) \cap P) \subseteq \sigma^0_m(M(q^0, q)) \times I_m^1 \]  

Since \( D_{1/0} : 1^0 \oplus 1^1 \) is a bounded linear operator, this implies the existence of a number \( M_1(g^0, q) \) such that

\[
\hat{\mathcal{U}}(A^0) \cap F^0, \ D(q) \cap F \subset \mathcal{C}_m(M_1(g^0, q)) \times \mathcal{C}_m(M_1(g^0, q)) .
\]  

(7.3.1)

Since the sets \( F^0 \) and \( F \) are supposed to be compact, a finite number of vectors \( (g_i^0, q_i) \in F^0 \times F \), \( i = 1, 2, \ldots, L \) exist (Heine-Borel) such that

\[
\bigcup_{i=1}^L \lambda(g_i^0) = \mathcal{U}(q_i) = F^0 \times F .
\]

(7.3.2)

The relations (7.3.1) and (7.3.2) imply the existence of a number \( M_1 \) such that

\[
\hat{\mathcal{U}}(F^0 \times F) \subset \mathcal{C}_m(M_1) \times \mathcal{C}_m(M_1) .
\]

Property b) for set \( \hat{\mathcal{U}}(F^0 \times F) \) then follows from the symmetry between primal and dual system.

(c) Since, for every \((e^0, p) \in F^0 \times F \), \( \hat{\mathcal{U}}(e^0, p) \) is the set of \( m \)-transforms of \( e^0 \)-optimal solutions, we have, for every \((e^0, p, u, v), (F^0, p, u, v) \in \text{graph} (F^0 \times F, \hat{\mathcal{U}})\):

\[
\hat{\varphi}(e^0, p) = \langle e^0, p, \hat{u}, \hat{v} \rangle .
\]

(7.3.3)

\[
\hat{\varphi}(F^0, p) = \langle F^0, p, \hat{u}, \hat{v} \rangle .
\]

(7.3.4)

\[
\hat{\varphi}(e^0, p) \leq \langle e^0, p, \hat{u}, \hat{v} \rangle .
\]

(7.3.5)

\[
\hat{\varphi}(F^0, p) \leq \langle F^0, p, \hat{u}, \hat{v} \rangle .
\]

(7.3.6)

The relations (7.3.3) and (7.3.6) imply

\[
\hat{\varphi}(e^0, p) - \hat{\varphi}(F^0, p) \leq \langle e^0, p, \hat{u}, \hat{v} \rangle .
\]

(7.3.7)
(7.3.4) and (7.3.5) imply
\[ -\hat{\phi}(\tilde{T}^0, p) + \hat{\phi}(\tilde{\tilde{T}}^0, p) \geq \langle \tilde{\tilde{T}}^0 - \tilde{T}^0, \omega_m \rangle , \quad (7.3.8) \]

From 7.3-b it follows:
\[ |\langle \tilde{T}^0 - \tilde{\tilde{T}}^0, \omega_m \rangle| \leq M_2 \langle \tilde{\tilde{T}}^0 - \tilde{T}^0, p \rangle \| \omega_m \| \quad (7.3.9) \]

The inequalities (7.3.7), (7.3.8) and (7.3.9) imply
\[ |\hat{\phi}(\tilde{T}^0, p) - \hat{\phi}(\tilde{\tilde{T}}^0, p)\| \leq M_2 \langle \tilde{\tilde{T}}^0 - \tilde{T}^0, p \rangle \| \omega_m \| \quad (7.3.10) \]

In connection with the symmetry between the primal and dual problem we may also conclude that a number \( \bar{N} \) exists such that, for every \( (\tilde{T}^0, \tilde{p}), (\tilde{\tilde{T}}^0, \tilde{\tilde{p}}) \in F^{0} \times P; \)
\[ |\hat{\phi}(\tilde{T}^0, \tilde{p}) - \hat{\phi}(\tilde{\tilde{T}}^0, \tilde{\tilde{p}})\| \leq \bar{N} \langle \tilde{\tilde{T}}^0 - \tilde{T}^0, p \rangle \| \omega_m \| \quad (7.3.11) \]

From (7.3.10) and (7.3.11) one may easily derive that property c) holds.

7.4 Proposition.

If the sets \( F^{0} \subset F^{m} \) and \( P \subset P^{m} \) satisfy the conditions 7.1-a, b, c, then the graph of the mapping \( X : F^{0} \times P \to \Pi (l^{m}) \) def 7.2.1 is weak* closed.

Proof.

Suppose \( \{ (\tilde{T}^i, \tilde{p}^i, x^i) \}_{i=1}^\infty \) is a sequence in the graph \( (F^{0} \times P; X) \) which converges weak* to a point \( (\tilde{T}^0, \tilde{p}^0, x^0) \); i.e.
\[ \{(\tilde{T}^i, \tilde{p}^i, x^i)\}_{i=1}^\infty \subset \text{graph} \ (F^{0} \times P; X) \quad (7.4.1) \]
\[ \exists (\tilde{T}^0, \tilde{p}^0, x^0) \in (F^{0} \times P; X), \quad i \to \infty . \quad (7.4.2) \]
For such a sequence we shall show successively:

1) $(\xi^0, \rho^0) \in F^0 \times P^0$

2) $\xi(t^i, x^i) = \xi(t, x) , 
    ~ i \rightarrow \infty.

3) $\rho_{t^i} \xi^i = \rho_{t^0} \xi^0 , 
    ~ i \rightarrow \infty.

4) $\rho_{t^i} x_i^i = \rho(t, x) , 
    ~ i \rightarrow \infty.

$(\xi^0, \rho^0, x^0) \in \text{graph } (F^0 \times P \times X)$

Then, from 5), (7.5.1) and from (7.5.2), we may conclude that graph $(F^0 \times P \times X)$ is weak$^*$ closed.

(1) This property immediately follows from (7.4.1), (7.4.2) and from the supposition that $F^0$ and $P$ are compact and so weak$^*$ compact as well.

(2) Since $(\xi^i, \rho^i) \in F^0 \times P$ and since the sets $F^0 \times P$ satisfy the conditions 7.1-a, b, c, it follows from Theorem 7.3-c that numbers $\bar{N}_1$ and $\bar{N}_2$ exist such that:

$$ |\xi(t^i, x^i) - \xi(t, x)| \leq \bar{N}_1 (\xi(t^i, x^i) - \xi(t, x)) + \bar{N}_2 (\rho(t^i, x^i) - \rho(t, x)) , 
    ~ i \geq 0. 
$$

(7.4.3)

Since the sets $F^0$ and $P$ are bounded, a number $\bar{N}_3$ exists such that:

$$(\xi^0, \rho^0) \in \sigma^0_\infty(N_3) \times \sigma^0_\infty(N_3). 
$$

(7.4.4)

The relations (7.4.3) and (7.4.4) imply:

$$ |\xi(t^i, x^i) - \xi(t, x)| \leq \bar{N}_1 (\xi(t^i, x^i) - \xi(t, x)) + \bar{N}_2 (\rho(t^i, x^i) - \rho(t, x)) + 2a \bar{N}_3 (t^i - t) \geq 0, T \geq 1. 
$$

(7.4.5)
From (7.4.3), (7.4.5) and from the supposition that 
\( p_m > 1 \), one may deduce that
\[ \tilde{\phi}(f^i, p^i) + \tilde{\phi}(r^0, p^0), \quad i \to \omega. \]

(3) Since (7.4.2) implies (1:270) that \( \{p^i\}_{i=1}^m \) and \( \{x^i\}_{i=1}^m \) are
located in bounded sets of \( [1, \infty) \), and since \( v := \gamma^0 \ominus \gamma^0 \), one can derive from (7.4.2):
\[ p^i - p^0, \quad i \to \omega, \]
\[ x^i - x^0, \quad i \to \omega. \hspace{1cm} (7.4.6) \]
Since \( \{p^i\}_{i=1}^m \) and \( \{x^i\}_{i=1}^m \) are located in bounded sets of \( [1, \infty) \),
and since
\[ |p^i - x^i| = |\tilde{\phi}(f^i, p^i) + \tilde{\phi}(r^0, p^0)|, \quad i \geq 0, \]
one can derive that (7.4.6) implies property 3.

(4) Since \( \tilde{\phi}(f^i, p^i) = \tilde{\phi}(f^i, p^i), \quad i \geq 1 \), this property immediately
follows from 2) and 3).

(5) This property follows immediately from 1), 4) and from
the definition of the mapping \( X \).

7.5 Proposition
If the set \( F^0 \subset \Pi^m \) satisfies the conditions 7.1-a,b,c, then
the graph of the mapping \( XY : F^0 \to \Pi(\Pi^m) \times \Pi(\Pi^m) \) (def 7.2.2)
is weak* closed.

Proof.
Suppose \( \{(f^i, x^i, y^i)\}_{i=1}^m \) is a sequence in the graph of \( XY \) which
converges weak* to a point \( (f^0, x^0, y^0) \); i.e.:
\[ \{(f^i, x^i, y^i)\}_{i=1}^m \subset \text{graph } (p^0; XY), \]
\[ (f^i, x^i, y^i) \to (f^0, x^0, y^0), \quad i \to \omega. \hspace{1cm} (7.5.1) \]
For such a sequence we shall show that:

1) \( f^0 \in F^0 \).

2) \( G_{1/\rho}^n y^0 = f^0 \).

3) \((f^0, x^0, y^0) \in \text{graph } (F^0;XY) \).

Then, from c), (7.5.1) and from (7.5.2), we may conclude that graph \((F^0;XY)\) is weak* closed.

(1) This property immediately follows from (7.5.1), (7.5.2) and from the supposition that \( F^0 \) is compact and so weak* compact as well.

(2) Since \( \left( (x^1, y^1)^n \right)^w \subset \text{graph } (F^0;XY) \), we have:

\[
\left\langle \frac{x^1}{\rho}, y^1 \right\rangle = f^1, \quad 1 \geq 1.
\]

(7.5.3)

Since \( G_{1/\rho}^n : l_1^m \rightarrow l_1^m \) is a bounded linear operator (Prop. 6.17) and in addition (prop. 6.18), for every \( \nu \in l_1^m, \xi \in l_1^m \),

\[
\left\langle \nu, G_{1/\rho}^n \xi \right\rangle = \left\langle G_{1/\rho}^n \nu, \xi \right\rangle.
\]

The relations (7.5.2) and (7.5.3) imply, for every \( \nu \in l_1^m \),

\[
\left\langle \nu, f^1 \right\rangle = \left\langle \nu, G_{1/\rho}^n y^0 \right\rangle w, \quad i = 1.
\]

Clearly,

\[
f^1 = G_{1/\rho}^n y^0, \quad i = 1.
\]

(7.5.4)

From (7.5.2) and from (7.5.4) we may conclude

\[
G_{1/\rho}^n y^0 = f^0.
\]

(7.5.5)

(3) The definition (7.1.2) of the mapping \( XY \) implies

\[
\left\{ (x^i, y^i)^n \right\}^w \subset l_1^m \times l_1^m.
\]
Since \( l^\infty_m \) and \( l^\infty_m \) are weak* closed and \((x^i, y^i) \not\in (x^0, y^0)\), \( i = -\infty \), we have:

\[
(x^0, y^0) \notin l^\infty_m \times l^\infty_m. \tag{7.5.6}
\]

On the ground that (7.5.5) and (7.5.6) we may conclude that \((x^0, x^0, y^0) \notin \text{graph} (F^0; XY)\).

7.6 Proposition.

If the sets \( F^0 \subset l^\infty_m \) and \( F \subset l^\infty_m \) satisfy the conditions

7.2-a, b, c, then the graph of the mapping

\( XY : F^0 \times F = l^\infty_m \times l^\infty_m \) (def 7.2.3) is weak* compact.

Proof.

From theorem 7.3-\( \tilde{b} \) and from (7.2.3) we may conclude that a number \( M \) exists such that

\[
\text{graph} (F^0 \times F, XY) = \text{graph} (F^0 \times F, X) \times l^\infty_m \cap
\]

\[
\cap \{(x^0, p, x, y) | (x^0, x, y) \in \text{graph} (F^0, XY), p \in F) \cap
\]

\[
\cap (F^0 \times F, \sigma^N_m(N) \times \sigma^N_m(N)) \}. \tag{7.6.1}
\]

Since \( F^0 \) and \( F \) are weak* compact, the sets of the right-hand side of (7.6.1) possess the following properties:

- the first set is weak* closed (prop. 7.4),
- the second set is weak* closed (prop. 7.5),
- the third set is weak* compact (Alaoglu's theorem 1:272).

Hence, we may conclude that \( \text{graph} (F^0 \times F, XY) \) is weak* compact.

7.7 Proposition.

If the sets \( F^0 \subset l^\infty_m \) and \( F \subset l^\infty_m \) satisfy the conditions

7.2-a, b, c, then the mapping \( XY : F^0 \times F = l^\infty_m \times l^\infty_m \)

(def 7.2.3) possesses the following property:
However, (7.7.5) implies \((\bar{x}, \bar{y}) \notin Q\); so the supposition leads to a contradiction.

7.8 Theorem.

If \(F^0 \subseteq 1^n_m\) and \(F \subseteq 1^n_m\) satisfy the conditions 7.2-\(a,b,c\), then the mappings \(XY : F^0 \times P \to \Pi(1^n_m) \times \Pi(1^n_m)\) (def 7.2.3) and \(UV : F^0 \times P \to \Pi(1^n_m) \times \Pi(1^n_m)\) possess the following property:

For every \((x^0, p) \in F^0 \times P\) and every open set \(Q_1 \subseteq 1^n_m \times 1^n_m\), \(Q_2 \subseteq 1^n_m \times 1^n_m\) such that \(Q_1 \supseteq \overline{XY}(x^0, p)\), \(Q_2 \supseteq \overline{UV}(x^0, p)\) a neighbourhood \(\Omega(x^0, p) \subseteq 1^n_m \times 1^n_m\) exists for which:

\[
\overline{XY}(\Omega(x^0, p) \cap F^0 \times P) \subseteq Q_1 \quad (7.8.1)
\]

\[
\overline{UV}(\Omega(x^0, p) \cap F^0 \times P) \subseteq Q_2 \quad (7.8.2)
\]

Proof.

Suppose that \((x^0, p) \in F^0 \times P\) and the open set \(Q_1 \subseteq 1^n_m \times 1^n_m\), \(Q_2 \subseteq 1^n_m \times 1^n_m\) are such that

\[
Q_1 \supseteq \overline{XY}(x^0, p) \quad (7.8.3)
\]

\[
Q_2 \supseteq \overline{UV}(x^0, p) \quad (7.8.4)
\]

Since every open set in \(1^n_m \times 1^n_m\) is also weakly open, we may conclude, by virtue of proposition 7.7, that a neighbourhood \(\Omega_1(x^0, p) \subseteq 1^n_m \times 1^n_m\) exists, such that

\[
\overline{XY}(\Omega_1(x^0, p) \cap F^0 \times P) \subseteq Q_1 \quad (7.8.5)
\]

Then, from the symmetry between the primal and dual systems, we also may conclude that a neighbourhood \(\Omega_2(x^0, p) \subseteq 1^n_m \times 1^n_m\) exists, satisfying
Putting \( \Omega(\xi, \eta) := \Omega_1(\xi, \eta) \cap \Omega_2(\xi, \eta) \), it follows from (7.8.5) and (7.8.6) that

\[
\Xi(\xi, \eta) \subset Q_1,
\]

\[
\Upsilon(\xi, \eta) \subset Q_2.
\]

7.9 Remark.

Theorem 7.8 is an analogy of the well known property of upper semicontinuity (1.11.3) of the set of optimal solutions of a LP-problem in a finite dimensional space. In order to formulate this property, consider the following LP-problem in a finite dimensional Euclidean space:

\[
\Phi(g, q) := \max_{x, y} q'x \quad \text{subject to} \quad cx + y = g, \quad x, y \geq 0,
\]  

(7.9.1)

\[
\Psi(g, q) := \min_{u, v} g'u - q \quad \text{subject to} \quad c'u - v = q, \quad u, v \geq 0,
\]  

(7.9.2)

where, \( q \in \mathbb{R}^n \), \( g \in \mathbb{R}^m \) and \( c \) is a \( n \times m \)-matrix.

Defining \( \Xi(\cdot) : \mathbb{R}^{m+n} \to \mathbb{R}^{m+n} \) and \( \Upsilon(\cdot) : \mathbb{R}^{m+n} \to \mathbb{R}^{m+n} \) by

\[
\Xi(g, q) := (x, y) \in \mathbb{R}^{m+n} \quad \text{subject to} \quad cx + y = g, \quad q'x = \Phi(g, q),
\]

\[
\Upsilon(q, g) := (u, v) \in \mathbb{R}^{m+n} \quad \text{subject to} \quad c'u - v = q, \quad g'u = \Psi(q, g),
\]

the following property holds:

If the systems
\[ cx+y = \overline{a}, \]
\[ x, y > 0 \}
\[ c'u - v = \overline{q}, \]
\[ u, v > 0 \}

are solvable, then for every open \( Q_1 \supset \overline{\Omega}(\overline{e}, \overline{q}) \) and every open \( Q_2 \supset \overline{\Omega}(\overline{e}, \overline{q}) \), a neighborhood \( \Omega(\overline{e}, \overline{q}) \subset \mathbb{R}^{m+n} \) exists such that
\[
\begin{align*}
\overline{\Omega}(\Omega(\overline{e}, \overline{q})) & \subset Q_1 \\
\overline{\Omega}(\Omega(\overline{e}, \overline{q})) & \subset Q_2
\end{align*}
\]

In that case, we say that \( XY \) and \( YZ \) are upper semicontinuous at \( (\overline{e}, \overline{q}) \).
8. PATHS OF EQUILIBRIUM.

8.1 Introduction.

In this chapter we consider a very special type of feasible solutions of the LP-problem (P - or D-directed; \( P^0 \)- and \( D \)-feasible; \( f(t) = \tilde{y}, p(t) = \tilde{y}, t \geq 1; \beta \tau < 1 \)). To that end, we investigate the following system:

\[
\begin{align*}
\begin{bmatrix}
\beta + \lambda \tilde{x} + \tilde{y} = \tilde{y} \\
\beta' - \lambda \tilde{z} = \tilde{y} \\
\tilde{y} - \tilde{x} + \tilde{y}' = 0
\end{bmatrix}
\end{align*}
\]

(8.1.1)

If \((\tilde{x}, \tilde{y}), (\tilde{z}, \tilde{v}) \in R^+ \) satisfies (8.1.1), then it may be verified that \((x, y) \) defined by

\[
(x(t), y(t)) = \beta^t (\tilde{x}, \tilde{y}), \quad t \geq 1
\]

(8.1.2)

is a \( P \)-feasible solution for the LP-system with an initial vector \( x(0) = \tilde{x} \), and that \((u, v) \), defined by

\[
(u(t), v(t)) = \tau^t (\tilde{u}, \tilde{v}), \quad t \geq 1
\]

(8.1.3)

is a \( D \)-feasible solution of this LP-system.

Moreover, \((x, y), (u, v) \) satisfies:

\[
\begin{align*}
< v, x >_T + < u, y >_T = & 0, \quad T \geq 0, \\
\tau(T-1)'Ax(T) = & 0, \quad T > 0, \\
< p_\tau, x >_T = & < p_\tau, x >_\infty, \quad T \to \infty, \\
< f_\tau, x >_T = & < f_\tau, x >_\infty, \quad T \to \infty, \\
< p_\tau, x >_\infty = & < f_\tau, x >_\infty, \quad (\text{proposition 4.2})
\end{align*}
\]
So, by virtue of theorem 6.5, we may conclude: \((x,y)\) is \(P\)-optimal and \((u,v)\) is \(D\)-optimal.

A combination of non-negative vectors \((\bar{x}, \bar{y}), (\bar{u}, \bar{v})\) satisfying (6.1.1) we shall call an equilibrium combination (\(\ast\)); the combination of vectors \(((x,y), (u,v))\), defined by (6.1.2) and (6.1.2), is called a path of equilibrium. Clearly, these concepts are only sensible for an LP-problem which is exponential (i.e.: \(f(t) = \bar{p}, p(t) = \bar{p}, t \geq 1\)).

First we shall prove that every LP-problem \((P\text{-} or D\text{-}directed; exponential; initial strong regular)\) possesses an equilibrium combination.

### 8.2 Definitions.

We consider, for all \(q \in \mathbb{R}^n\), the following linear programming problem in a finite dimensional Euclidean space:

\[
\varphi(q) := \max_{x,y} \langle \bar{x} - q, x \rangle \quad \text{s.t.} \quad (\bar{y} - \frac{1}{2}A)x + y = \bar{z}, \quad x \in \mathbb{R}_+, \quad y \in \mathbb{R}_+^n.
\]

\[(8.2.1)\]

\[
\psi(q) := \min_{u,v} \langle \bar{u} - q, u \rangle - \langle v, \bar{v} \rangle \quad \text{s.t.} \quad (\bar{y} - \frac{1}{2}A)u - v = \bar{z}, \quad u \in \mathbb{R}_+, \quad v \in \mathbb{R}_+^n.
\]

\[(8.2.2)\]

We shall memorize some properties of these problems:

a) Problem (8.2.1) or (8.2.2) possesses an optimal solution, if and only if the problems are both feasible. In that case: \(\varphi(q) = \psi(q)\).

b) Feasible solutions \((\bar{x}, \bar{y})\) and \((\bar{u}, \bar{v})\) of (8.2.1), (8.2.2) resp. are both optimal, if and only if

\((\ast)\) in some degree, this problematic is related to that treat-
ed by Von Neumann: "A model of general economic equilibrium". (11)
\[ \overline{w}x + \overline{w}y = 0. \]

c) If (8.2.1) possesses a feasible solution \( x, y > 0 \), and

\( Q \subseteq \mathbb{R}^n \) is a compact set such that, for every \( q \in Q \),

problem (8.2.2) has a feasible solution \( u, v \geq 0 \), then the

mappings \( \overline{x} : \mathbb{R}^n \rightarrow \mathbb{R}(\mathbb{R}^n), \overline{u} : \mathbb{R}^n \rightarrow \mathbb{R}(\mathbb{R}^n) \) defined by:

\[
\overline{x}(q) : = \begin{cases} x & \text{if } 0 < x, \\ \infty & \text{otherwise}, \end{cases}
\]

\[ (B - \frac{1}{\overline{c}}A)x \leq B - \frac{1}{\overline{c}}b - \overline{d}. \]  

\[
\overline{u}(q) : = \begin{cases} u & \text{if } 0 < u, \\ \infty & \text{otherwise}. \end{cases}
\]

\[ (B' - \frac{1}{\overline{c}'}A')u \geq B' - \frac{1}{\overline{c}'}b' - \overline{d'}, \]  

are upper semicontinuous on \( Q \) (see §7.9). Note: \( \overline{x}(q) \) and \( \overline{u}(q) \) are the sets of optimal solutions of (8.2.1), (8.2.2) resp.

Further, we introduce the matrices \( C \) (n×m) and \( D \) (diagonal m × m):

\[
c_{ij} = \begin{cases} \frac{1}{\overline{c}}b_i & \text{if } b_i > 0, \\ 0 & \text{else} \end{cases}
\]

\[
c_{ij} = \begin{cases} \frac{1}{\overline{c}'}b_i' & \text{if } b_i' > 0, \\ 0 & \text{else} \end{cases}
\]

\[
d_{ii} = \frac{1}{\overline{c}}, \quad \text{if } b_i > 0,
\]

\[ d_{ii} = 1, \quad \text{if } b_i > 0. \]

These definitions imply:

\[ (B - \frac{1}{\overline{c}}A)C = U(B - \frac{1}{\overline{c}'}A). \]  

If \( pm < 1 \) and if the LP-problem is P-directed (§7.9), then

(8.2.5) implies:

\[ C \geq 0. \]  

(8.2.8)
With the help of these definitions, we find the following relation between system (8.1.1) and the problems (8.2.1), (8.2.2).

8.3 Proposition.

System (8.1.1) possesses a nonegative solution, if and only if a $q \in \mathbb{R}^n$ exists, such that the corresponding problem (8.2.2) possesses an optimal $(u_q, v_q)$ which satisfies

$$C^t u_q = q.$$  \hspace{1cm} (8.3.1)

Proof.

Necessary: Let $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ be a nonnegative solution of (8.1.1) then $(\check{x}, \check{y}, \check{u}, \check{v})$ satisfy:

\[
\begin{align*}
\tilde{y}^t X \tilde{u} &= 0 \\
(\gamma - \frac{1}{2} \Lambda) \tilde{y} &= \check{y} \\
(\gamma - \frac{1}{2} \Lambda^t) D^t \tilde{u} &= \check{v} - C \check{u}^t \check{u}
\end{align*}
\]

in which the last equality is implied by (8.2.7). From this, by virtue of 8.2.-b, we may conclude: $(\tilde{u}, \tilde{v}) := (D^t \tilde{u}, \check{v})$ is an optimal solution of problem (8.2.2) with $q = C^t \tilde{u}$.

Sufficient: Suppose that, for some $q \in \mathbb{R}^n$, problem (8.2.2) possesses an optimal solution $(\check{u}, \check{v})$ such that

$$C^t u_q = q.$$  \hspace{1cm} (8.3.2)

Then, by virtue of 8.2.-a,b, we may conclude that problem (8.2.1) possesses an optimal solution $(x_q, y_q)$; i.e.:

\[
\begin{align*}
\tilde{y}^t X_q \tilde{v} &= 0 \\
(\gamma - \frac{1}{2} \Lambda) x_q &= \check{y}_q
\end{align*}
\]
Equality (8.1.7) implies

\[(B' - \lambda A')u_q - v_q = (B' - \lambda A')Du_q - C'u_q - v_q = \bar{v}' - q', \]

and so, by virtue of (8.3.2):

\[(B' - \lambda A')(Du_q - v_q) = \bar{u}' . \]

Clearly, \((x_q, y_q), (Du_q, v_q)\) is a non-negative solution of (8.1.1).

8.4 Definition.

The consequence of proposition 8.3 is, that instead of system (8.1.1) we may consider the linear programming problems (8.2.1) and (8.2.2).

In order to investigate the existence of a \(q \in \mathbb{R}^n\) as mentioned in proposition 8.3, we introduce the mapping \(\mathbb{W} : \mathbb{R}^n \to \mathbb{P}(\mathbb{R}^m)\), defined by:

\[\mathbb{W}(q) = \{u = C'u \mid u \in \mathbb{U}(q)\} , \tag{8.4.1}\]

where, \(\mathbb{U} : \mathbb{R}^n \to \mathbb{P}(\mathbb{R}^m)\) is defined in 8.2-c.

8.5 Proposition.

If a set \(Q\) exists which possesses the following properties:

a) \(Q\) is compact and convex,

b) For every \(q \in Q\), the problems (8.2.1), (8.2.2) have feasible solutions \((x, y) > 0, (u, v) > 0\), resp.

c) \(\mathbb{W}(Q) \subseteq Q\),

then, system (8.1.1) possesses a non-negative solution.

Proof.

By virtue of 8.2-c, supposition b implies that \(\mathbb{U} : Q \to \mathbb{P}(\mathbb{R}^m)\) is upper semicontinuous on \(Q\). This implies \(\mathbb{W} : Q \to \mathbb{P}(\mathbb{R}^m)\) is
upper semicontinuous as well.

The convexity of $W(q)$ for every $q \in Q$ implies that $W(q)$ is convex for every $q \in Q$.

Thus, we have the following properties:
- $Q$ is compact and convex (by supposition a),
- for every $q \in Q$: $W(q)$ non-empty and convex,
- $W : Q \rightarrow \mathbb{R}^n$ is upper semicontinuous,
- $W(Q) \subseteq Q$ (by supposition c).

Then, Kakutani's fixed point theorem (6.67) implies the existence of $q$ such that

$$ q \in W(q). $$

In connection with the definition of $W$, this implies the existence of a $q \in W(q)$, such that $C'q = q$ and so, by virtue of proposition 8.3, the existence of a non-negative solution for (8.1.1).

3.6 Proposition.

If: $C \geq 0$ (def 8.1.5) and if the systems

$$ (B' - \frac{1}{\rho}A')xy = \bar{y}, $$
$$ x, y > 0, $$

$$ (B' - \frac{1}{\rho}A')uv = \bar{p}, $$
$$ u, v > 0, $$

are solvable, then the system (8.1.1) possesses a non-negative solution.

Proof.

We shall construct a set $Q \subseteq \mathbb{R}^n$ which satisfies the conditions
formulated in proposition 8.5.

Let \((y, z)\) be a solution of (8.6.1) then, for every 
\((q, u_q) \in \text{graph}(R_q, \bar{y})\):

\[
\begin{align*}
\hat{z} q' u_q &= ((\lambda - \frac{1}{2} A C \lambda + y) q' u_q = \\
&= \lambda'(y' (\lambda - \frac{1}{2} A C \lambda + y) q' u_q + (y' + z' C') q' u_q) x \\
&\geq (\lambda - q') (y' + z' C') q' u_q,
\end{align*}
\] (8.6.3)

Let \((y, z)\) be a solution of (8.6.2), then we may conclude successively: \(\mu\) is a feasible solution of (8.2.2) if \(q = 0\); \(\mu\) is a feasible solution of (8.2.2) if \(q \in R_q^0\); \(\hat{y}' \mu \geq \hat{y}' u_q\) for every 
\(u_q \in \text{graph}(R_q, \bar{y})\); and finally, by virtue of (8.6.3):

\[
\hat{y}' \mu \geq (\lambda - q') (y' + z' C') q' u_q,
\] (8.6.4)

for every \((q, u_q) \in \text{graph}(R_q, \bar{y})\).

Since \(\lambda > 0\), on \(\epsilon > 0\) (small enough) exists such that 
\(y' + z' C \geq (1 + \epsilon) y' + z' C'\). This implies by virtue of (8.6.4):

\[
x' C' q' u_q \leq \frac{1}{1 + \epsilon} x' (y' + z' C') u_q \leq \frac{1}{1 + \epsilon} (\hat{y}' u_q - y' u_q),
\] (8.6.5)

for every \(q, u_q \in \text{graph}(R_q, \bar{y})\).

Now define set \(Q \subset R_q^0\) as follows:

\[
Q := \{ q \in R_q^0 \mid x' q \leq \frac{1}{1 + \epsilon} (\hat{y}' u_q - y' u_q) \}.
\] (8.6.6)

Then (8.6.5) implies:

\[
x' C' q' u_q \leq \frac{1}{1 + \epsilon} x' (y' + z' C') u_q \leq \frac{1}{1 + \epsilon} (\hat{y}' u_q - y' u_q) = \frac{1}{\epsilon} (\hat{y}' u_q - y' u_q),
\] (8.6.7)

for every \((q, u_q) \in \text{graph}(Q, \bar{y})\).
Since $U : R^p \rightarrow \Pi(R^p)$ is defined (8.6.1) by

$$U(q) := \{u = C^t u \mid u \in U(q)\}.$$

we may conclude from (8.6.6) and (8.6.7):

$$U(Q) \cap \mathbb{R}^p_+ \subseteq Q.$$

Since, by supposition, $C \geq 0$ and since $U(Q) \subseteq \mathbb{R}^p_+$, definition (8.6.8) implies $U(Q) \subseteq \mathbb{R}^p_+$. Hence, we may conclude

$$U(Q) \subseteq Q.$$

Since $A > 0$ and since $(f'w - f'y) > 0$ (from (8.6.4)) by putting $q = (0)$, definition (8.6.6) implies that $Q$ is compact, convex and non-empty. Moreover, since $Q \subseteq \mathbb{R}^p_+$ and $C \geq 0$, the solvability of (8.6.1) and (8.6.2) implies that the programming problem (8.2.1) and (8.2.2) possess a feasible solution $(x, y) > 0$, $(u, v) > 0$ for every $q \in Q$. Hence, by virtue of proposition 8.5, we may conclude; system (8.1.1) possesses a non-negative solution.

8.7 Theorem.

An LP-problem (P̂ or D-directed; $f(t) = \frac{2}{3}$, $p(t) = \frac{3}{2}$, $t \geq 1$; virtually superregular) possesses an equilibrium combination.

Proof.

Since the LP-problem is supposed to be initial strong regular and P̂ or D-directed, the systems

$$\begin{align*}
(B - \bar{A}) x + y &= \frac{2}{3} \\
&\text{subject to} \ x, y > 0,
\end{align*}$$

and

$$\begin{align*}
\left(\begin{array}{cc}
B' & \bar{A}' \\
\bar{p} & \bar{p}
\end{array}\right) u - v &= \frac{3}{2} \\
u, v > 0,
\end{align*}$$

```
are solvable (3.10-e).

Now, suppose that the LP-problem is P-directed, then the def-
inition of P-directedness in 52.7, the definition (8.2.6) of
matrix D, and the inequality \( \rho u < 1 \), imply:

\[ D^{\frac{1}{2}} \leq \left( \frac{1}{\rho} \right)^{\frac{1}{2}}. \]  

(8.7.3)

Let \((x, y)\) be a solution of (8.7.1), then:

\[ D(B - \rho A)x + Dy = 0. \]

Then, from inequality (8.7.3) and from equality (8.2.7), we
may conclude:

\[ (B - \rho A)x + Dy \leq \left( \frac{1}{\rho} \right)^{\frac{1}{2}}. \]

(8.7.4)

In connection with the definition of \( D \), the latter inequality
implies the solvability of the system

\[
\begin{align*}
(B - \rho A)x + y &= y' \\
x, y &> 0
\end{align*}
\]  

(8.7.4) since \( C \geq 0 \) (8.2.8), and since the systems (8.7.2) and (8.7.4)
are solvable, we may conclude, by virtue of proposition 8.6,
that the LP-problem possesses an equilibrium combination, in
case P-directedness is supposed.

Now, suppose that the LP-problem is D-directed, then, if we
write (8.1.1):

\[
\begin{align*}
\left( \lambda' - \frac{1}{\rho} B \right) x + y &= \left( -\rho P \right) \\
\left( A - \rho B \right) x + y &= \left( -\rho I \right) \\
y' + x + y &= 0
\end{align*}
\]  

it is clear that the LP-problem also possesses an equilibrium
combination.
9. **SEMI-EQUILIBRIUM PATHS**.

9.1 **Introduction.**

Let $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ be an equilibrium combination of an LP-problem (exponential), then every feasible solution $((x,y),(u,v))$ such that

\[
\begin{align*}
\langle \tilde{y}, \tilde{u} \rangle^T (x(t), y(t)) &= 0 \\
\langle \tilde{y}, \tilde{u} \rangle^T (u(t), v(t)) &= 0
\end{align*}
\]

is called a semi-equilibrium path of $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$.

In accordance with §4.1, we call a semi-equilibrium path $((x,y),(u,v))$ consistent if simultaneously: $\{p_x, x\}_T^\infty$ has a lower bound and $\{\bar{p}_u, u\}_T^\infty$ has an upper bound.

In this chapter, we shall especially investigate semi-equilibrium paths belonging to an equilibrium combination $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ which possesses the following properties:

a) $(\tilde{x}, \tilde{y})$ contains exactly $m$ positive components.

b) $(\tilde{u}, \tilde{v})$ contains exactly $n$ positive components.

c) Given $(\tilde{u}, \tilde{v})$, the primal part $(\tilde{x}, \tilde{y})$ is unique, i.e.: no equilibrium combination $(x, y), (u, v), (x, y) \neq (\tilde{x}, \tilde{y})$ exists.

d) Given $(\tilde{x}, \tilde{y})$, the dual part $(\tilde{u}, \tilde{v})$ is unique, i.e.: no equilibrium combination $(x, y), (u, v), (u, v) \neq (\tilde{u}, \tilde{v})$ exists.

Such an equilibrium combination is called **non-degenerated**.

9.2 **Theorem.**

If $((x,y),(u,v))$ is a consistent semi-equilibrium path of an LP-problem (or $\Delta$-directed; exponential; virtually superregular) then, $x, y$ are $\gamma$-dominated and $u, v$ are $\tau$-dominated.

**Proof.**

Let $((x,y),(u,v))$ be a consistent semi-equilibrium path of an
LP-problem (P- or D-directed; \( f(t) = \hat{f}, p(t) = \hat{p}, t \geq 1 \): virtually superregular) belonging to an equilibrium combination \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\). Then the following holds:

\[
(B' - \rho A') \tilde{u} - \tilde{v} = \hat{y},
\]

\[
\tilde{y}^T \tilde{x}(t) = 0, \quad t \geq 1,
\]

\[
\tilde{u}^T \tilde{y}(t) = 0, \quad t \geq 1.
\]

\[
(B - \hat{\lambda} A) (\frac{1}{\rho} t - \hat{\lambda} A) \tilde{x}(t) = \hat{b}(\frac{1}{\rho} t - \hat{\lambda} A(0)) + \int_{t}^{\infty} \left( \frac{1}{\rho} t - \hat{\lambda} A(t) \right) \tilde{y}(t)
\]

\[
= \left( \frac{1}{\rho} t - \hat{\lambda} A(0) \right) \tilde{x}(t) + \int_{0}^{\infty} \left( \frac{1}{\rho} t - \hat{\lambda} A(t) \right) \tilde{y}(t),
\]

where the latter inequality may be written by virtue of the fact that consistency implies \( x_{t} \in \mathbb{L}^2 \), \( y_{t} \in \mathbb{L}^2 \) (Theorem 4.9).

We choose \( a \in [0, \rho] \) in such a manner that

\[
(B' - \rho A') u - v = \hat{y},
\]

possesses a solution \( u, v > 0 \). This is possible, since the LP-problem is supposed to be P- or D-directed and virtually superregular, which implies (§3.10) that

\[
(B' - \rho A') u - v = \hat{y}, \quad u, v > 0.
\]
is solvable.

Now, suppose that \(x, y\) are not \(\rho\)-dominated, then the sequence 
\((\eta(T))_n^{\infty}\) defined by:
\[
\eta(T) := \left( \frac{2}{p} \right) \sum_{t=1}^{T} \left( \frac{1}{\alpha} \right)^t x(t) \frac{i}{I_i} + \left( \frac{1}{\rho} \right)^{T} x(T) I_i + \left( \frac{1}{\rho} \right) \sum_{t=T+1}^{\infty} \pi^t y(t) I_i \ , \quad T \geq 1 , \tag{5.2.7}
\]
contains a subsequence \((\eta(T_k))_k^{\infty}\) such that
\[
\eta(T_{k+1}) > \eta(T_k) > 0 , \quad k \geq 1 , \tag{5.2.8}
\]
and such that \((\eta(T_k))_k^{\infty}\) has no upper bound.

When we define the sequences
\[
x^1(k) := \left( \frac{1}{\eta(T_k)} \right) \left( \frac{2}{p} \right) \sum_{t=1}^{T_k} \left( \frac{1}{\alpha} \right)^t x(t) , \quad k \geq 1 ,
\]
\[
x^2(k) := \frac{1}{\eta(T_k)} \left( \frac{1}{\rho} \right)^{T_k} x(T_k) , \quad k \geq 1 ,
\]
\[
x^3(k) := \frac{1}{\eta(T_k)} \left( \frac{1}{\rho} \right) \sum_{t=T_k+1}^{\infty} \pi^t x(t) , \quad k \geq 1 ,
\]
\[
y^1(k) := \left( \frac{1}{\eta(T_k)} \right) \left( \frac{2}{p} \right) \sum_{t=1}^{T_k} \left( \frac{1}{\alpha} \right)^t y(t) , \quad k \geq 1 ,
\]
\[
y^2(k) := \frac{1}{\eta(T_k)} \left( \frac{1}{\rho} \right)^{T_k} y(T_k) , \quad k \geq 1 ,
\]
\[
z^1(k) := \frac{1}{\eta(T_k)} \left( \frac{1+1/a}{a} \right) \sum_{t=1}^{T_k} \left( \frac{2}{p} \right) \sum_{t=T_k+1}^{\infty} \pi^t A x(t) , \quad k \geq 1 ,
\]
\[
z^2(k) := \frac{1}{\eta(T_k)} \left( \frac{1}{1-\rho} \right) ,
\]
then it follows from (9.2.2) to (9.2.5), and from definition (9.2.7) that:

\[
\begin{align*}
& (\alpha - \frac{1}{u}A)x_1(k) + \beta x_2(k) + y_1(k) = \ell_1(k) \\
& (\beta - \frac{1}{u}A)x_3(k) - \alpha x_2(k) + y_2(k) = \ell_2(k) \\
& x_1(k), x_2(k), x_3(k), y_1(k), y_2(k) \geq 0 \\
& \exists \lambda_1 \geq 1, \quad \lambda x_1(k) = \lambda x_2(k) = \lambda x_3(k) = 0 \\
& \Lambda y_1(k) = \Lambda y_2(k) = 0 \\
& \Lambda x_1(k) + x_2(k) + y_1(k) + y_2(k) \leq 1 \\
& \ell_1(k) = 0, \quad k = 1, \\
& \ell_2(k) = 0, \quad k = 1.
\end{align*}
\]

This implies the existence of subsequences \(\{x_1(k_h)\}_{h=1}^\infty, \{x_2(k_h)\}_{h=1}^\infty,\)
\(\{x_3(k_h)\}_{h=1}^\infty, \{y_1(k_h)\}_{h=1}^\infty, \) and \(\{y_2(k_h)\}_{h=1}^\infty\) which converge to vectors \(x_1, x_2, x_3, y_1\) and \(y_2\) resp. satisfying:

\[
\begin{align*}
& (\alpha - \frac{1}{u}A)x_1 + \beta x_2 + y_1 = 0, \quad (9.2.9) \\
& (\beta - \frac{1}{u}A)x_3 - \alpha x_2 + y_2 = 0, \quad (9.2.10) \\
& x_1, x_2, x_3, y_1, y_2 \geq 0, \quad (9.2.11) \\
& \Lambda x_1 + \Lambda x_2 + y_1 + y_2 \leq 1, \quad (9.2.12) \\
& \Lambda y_1 = \Lambda y_2 = \Lambda x_3 = 0, \quad (9.2.13) \\
& \Lambda y_1 = \Lambda y_2 = 0, \quad (9.2.14)
\end{align*}
\]

The equalities (9.2.9) and (9.2.10) imply
\[(B-A)(x^1+x^2+x^3)+(y^1+y^2) = \left(\frac{1}{\alpha}-y\right)Ax^1.\]  
\hspace{1cm} (9.2.15)

The equalities (9.2.1), (9.2.15), (9.2.13) and (9.2.14) imply:
\[\tilde{p}'(x^1+x^2+x^3) = \left(\frac{1}{\alpha}-y\right)\tilde{u}'Ax^1.\]  
\hspace{1cm} (9.2.16)

In case the LP-problem is P-directed (9.2.9) implies:
\[Ax^1 \geq 0.\]  
\hspace{1cm} (9.2.17)

In case the LP-problem is D-directed (9.2.1) implies:
\[A'u + \tilde{v} \geq 0.\]  
\hspace{1cm} (9.2.18)

Since \(\tilde{v}'x^1 = 0\), the inequalities (9.2.17) and (9.2.18) both imply:
\[u'Ax^1 \geq 0.\]  
\hspace{1cm} (9.2.19)

Since \(\frac{1}{\alpha} > \tau\), it follows from (9.2.16) and from (9.2.19) that:
\[\tilde{p}'(x^1+x^2+x^3) \geq 0.\]  
\hspace{1cm} (9.2.20)

Now, suppose that the LP-problem is P-directed. Then, equality (9.2.10) and \(\left(\frac{1}{\alpha}-y\right) > 0\) imply:
\[-(\frac{1}{\alpha}-y)A(x^2+x^3) \leq 0.\]  
\hspace{1cm} (9.2.21)

Adding (9.2.9), (9.2.10) and (9.2.21) we find:
\[\left(\frac{\alpha-1}{\alpha}A\right)(x^1+x^2+x^3)+(y^1+y^2) \leq 0.\]  
\hspace{1cm} (9.2.21)

Then, by virtue of Stienkes theorem (page 31), it follows from (9.2.20), (9.2.21), (9.2.12), and (9.2.11) that system
\[\begin{cases} (B-A)u-v = \tilde{p} \\ u, v > 0 \end{cases}\]
is non-solvable. However, \( \alpha \) is chosen in such a manner that (9.2.6) possesses a solution \( u, v > 0 \). Thus, the suppositions that the LP-problem is D-directed and that \( x, y \) are not \( \theta \)-dominated give rise to contradictoriness.

Now, consider the case that the LP-problem is D-directed. The equalities (9.2.9) and (9.2.10) imply:

\[
(\beta - \frac{1}{A})y^1 + (5 - \frac{1}{A})y^2 + x^3 = 0
\]

(9.2.22)

By virtue of Hille's theorem, it follows from (9.2.22), (9.2.10), (9.2.11), and from (9.2.12), that the system

\[
\begin{align*}
(B^t - \frac{1}{A'}^t)u^1 - v^1 &= \varepsilon \\
(B^t - \frac{1}{A'}^t)u^2 - v^2 &= \varepsilon \\
u^1, v^1, v^2 &> 0
\end{align*}
\]

(9.2.23)

is non-solvable. However, if \( (u, v) > 0 \) is a solution of (9.2.6) then D-directedness implies that \( u^1 := u, v^1 := v, v^2 := v + (\frac{1}{A'})^t A' \), is a solution of (9.2.23). Hence, the suppositions that the LP-problem is D-directed and that \( x, y \) are not \( \theta \)-dominated give rise to contradictoriness.

The theorem with respect to the dual part of a semi-equilibrium path, follows from the validity of the theorem for the primal part and from the symmetry between the primal and dual systems.

9.3 Definitions.

From now on, we shall consider semi-equilibrium paths belonging to a non-degenerated equilibrium combination.

The definition of a non-degenerated equilibrium combination \( (\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v}) \) implies:
- components \( \tilde{x} \) and \( \tilde{y} \) cannot be simultaneously zero,
- components \( \tilde{u} \) and \( \tilde{v} \) cannot be simultaneously zero.
This implies the following relations:
- If \( x \) possesses \( k \) positive components, then:
  - \( y \) has \( m-k \) positive components,
  - \( u \) has \( k \) positive components,
  - \( v \) has \( n-k \) positive components.

We define the following quantities:

a) \( m \times k \)-matrix \( S_p \), consisting of the column vectors of the
\( m \times m \)-identity matrix which correspond in the same order
with the positive components of \( y \),

b) \( k \times m \)-matrix \( S_d \), consisting of the row vectors of the \( m \times m \)-identity
matrix which correspond in the same order with the positive
components of \( u \),

c) The \( k \times k \) matrices \( A \) and \( B \) by:

\[
A := S_d A S_p \\
B := S_d B S_p
\]

d) The sets \( \mathcal{X} \subseteq \mathbb{R}^n \times \mathbb{R}^n \) and \( \mathcal{Y} \subseteq \mathbb{R}^n \times \mathbb{R}^n \) by:

\[
\mathcal{X} := \left\{ (x,y) \in \mathbb{R}^n \times \mathbb{R}^n \left| \begin{array}{l}
x(t) = S_p x(t), \ t \geq 1, \ x \in \mathbb{R}^k \\
y(t) = 0, \ t \geq 1
\end{array} \right. \right\}
\]

\[
\mathcal{Y} := \left\{ (u,v) \in \mathbb{R}^n \times \mathbb{R}^n \left| \begin{array}{l}
u(t) = S_d u(t), \ t \geq 1, \ u \in \mathbb{R}^k \\
v(t) = 0, \ t \geq 1
\end{array} \right. \right\}
\]

Now, vectors \((x,y) \in \mathcal{X}\) and \((u,v) \in \mathcal{Y}\) will be
considered, satisfying the following systems:

\[
\begin{align*}
Bx(t+1) - Ax(t)y(t+1) & = \rho^t e \psi \\
B'v(t) - A'u(t+1) - v(t) & = \pi \rho
\end{align*}
\]

(9.3.1)
9.4 Proposition.

If \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) is a non-degenerated equilibrium combination, then the corresponding systems (9.3.1), (9.3.2), and corresponding sets \(\tilde{X}, \tilde{Y}\), possess the following properties:

a) A vector \(((x, y), (u, v)) \in (l^n \times l^n) \times (l^n \times l^n)\) satisfies:

\[
\begin{align*}
&x(t), y(t), u(t), v(t) \geq 0 \\
&\langle \tilde{y}, \tilde{u} \rangle ' (x(t), y(t)) = 0 \\
&\langle \tilde{y}, \tilde{u} \rangle ' (u(t), v(t)) = 0
\end{align*}
\]

if and only if

\[
((x, y), (u, v)) \subseteq (\tilde{X} \cap l^n \times l^n) \times (\tilde{Y} \cap l^n \times l^n). \tag{9.4.2}
\]

b) If a vector \(((x, y), (u, v)) \in \tilde{X} \times \tilde{Y}\) satisfies (9.3.1), then

\[
\begin{align*}
x(t) \overset{\text{def}}{=} \tilde{S} x(t) \\
y(t) \overset{\text{def}}{=} \tilde{S} y(t)
\end{align*}
\]

satisfies (9.3.2).

c) If \((x, u)\) satisfies (9.3.2) then system (9.3.1) possesses a solution \(((x, y), (u, v))\), satisfying (9.3.1) and:

\[
\begin{align*}
x(t) \overset{\text{def}}{=} \tilde{S} x(t) \\
u(t) \overset{\text{def}}{=} \tilde{S} u(t)
\end{align*}
\]

Moreover, \(((x, y), (u, v)) \in \tilde{X} \times \tilde{Y}\).
Proof.

(a) **Necessary:** If \((x,y),(u,v)\) satisfies (9.4.1), then the non-degenerateness of \((\tilde{x},\tilde{y}), (\tilde{u},\tilde{v})\) implies that all components of \((x(t),y(t)), (u(t),v(t))\), \(t \geq 1\), corresponding with components \((\tilde{x},\tilde{y})_1 = 0\), \((\tilde{u},\tilde{v})_1 = 0\) resp., are zero. Then, definition 9.3-a,b implies:

\[
\begin{aligned}
&x(t) = S_p S_p' x(t) \\
&y(t) = 0 \\
&u(t) = S_d S_d' u(t) \\
&v(t) = 0
\end{aligned}
\]  

(9.4.5)

From (9.4.5), 9.3-d, and from the non-negativity of \(x,y\), \(u,v\), we may conclude that (9.4.2) is valid.

(b) **Sufficient:** Definition 9.3-c implies that \(\tilde{v}' S_p = 0\) and \(S_d' \tilde{v} = 0\). Hence, we may conclude that for all vectors \((x,y) \in \tilde{X} \tilde{Y}\) and \((u,v) \in \tilde{U} \tilde{V}\):

\[
\begin{aligned}
&\tilde{v}'(x(t),y(t)) = 0 \\
&\tilde{v}'(u(t),v(t)) = 0
\end{aligned}
\]  

(9.4.6)

(b) The definitions 9.3-a,b,c imply that all vectors \((x,y) \in \tilde{X} \tilde{Y}\) and \((u,v) \in \tilde{U} \tilde{V}\) satisfy (9.4.5). This implies for every \((x,y),(u,v)) \in \tilde{X} \tilde{Y} \times \tilde{U} \tilde{V}\) which satisfies (9.3.1):

\[
\begin{aligned}
&S_p S_p' x(t+1) - A S_p S_p' x(t) = \rho^{t+1} S_p \\
&S_d S_d' u(t+1) - A S_d S_d' u(t) = \pi^{t+1}
\end{aligned}
\]  

(9.4.6)

and so,

\[
\begin{aligned}
&S_p S_p' x(t+1) - (S_p A S_p)' x(t) = \rho^{t+1} S_p \\
&S_d S_d' u(t+1) - (S_d A S_d)' u(t) = \pi^{t+1}
\end{aligned}
\]  

(9.4.7)
Clearly, \((x, y)\), defined by \((9.4.3)\), satisfies \((9.3.2)\).

(c) If \((x, u)\) satisfies \((9.3.2)\), then \((x, u)\) defined by \((9.4.4)\) satisfies:

\[
\begin{align*}
S_{u}^{\text{t}} u(t+1) - S_{u}^{\text{t}} u(t) &= \rho^{t+1} S_{u}^{\text{t}} u(t) \\
S_{p}^{\text{t}} u(t) - S_{p}^{\text{t}} u(t+1) &= \pi^{t} S_{p}^{\text{t}} u(t) \\
\end{align*}
\]

\(t \geq 1\). \((9.4.8)\)

Clearly, for this unique \((x, u)\), a unique \((y, v)\) exists such that \((x, y), (u, v)\) satisfies \((9.3.1)\). Moreover, \((9.4.8)\) implies:

\[
\begin{align*}
S_{u}^{\text{t}} y(t) &= 0 \\
S_{p}^{\text{t}} v(t) &= 0 \\
\end{align*}
\]

\((9.4.9)\)

From \((9.4.4)\) and from \((9.4.9)\), we may conclude that

\[((x, y), (u, v)) \in \mathcal{X} \times \mathcal{Y} \times \mathcal{U} \times \mathcal{V}\]

9.5 Proposition.

If \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) is a non-degenerated equilibrium combination, then the matrices \((\overline{B}^{-1} A)\) and \((\overline{B}^{-1} A)\) defined by \(9.3.2\) are both invertible.

Proof.

Suppose that matrix \((\overline{B}^{-1} A)\), belonging to a non-degenerated equilibrium combination \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\), is not invertible. Then a vector \(\lambda \neq 0\) exists such that

\[\overline{B}^{-1} A \lambda = 0\] \((9.5.1)\)

This implies that, for every \(\lambda \in \mathbb{R}^{1}\):

\[S_{u}(\overline{B}^{-1} A)(\tilde{x}^{*} + \lambda S_{p}^{n} x) = S_{u}^{\text{t}} P\]

\]
Then, from the definitions 9.3-a,b, we may conclude that a vector $x$ exists, such that for every $\lambda$:
\[
\begin{align*}
(\mathbf{B} - \lambda \mathbf{A})(\tilde{x} + \lambda \tilde{y}_2) + (\tilde{y} + \lambda \tilde{y}_2) &= \tilde{z} \\
(\tilde{y}, \tilde{u})'(\tilde{x} + \lambda \tilde{y}_2, \tilde{y} + \lambda \tilde{y}_2) &= 0
\end{align*}
\]
(9.5.2)

Since $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ is non-degenerated, the definitions 9.3-a,b imply:
- for every component $\tilde{x}_i = 0$: $(\tilde{y}, \tilde{u}) = 0$,
- for every component $\tilde{y}_i = 0$: $\tilde{z}_i = 0$.

In connection with the non-negativity of $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$, this implies the existence of a $\lambda \neq 0$ (small enough) such that
\[
(\tilde{x} + \lambda \tilde{y}_2, \tilde{y} + \lambda \tilde{y}_2) \geq 0.
\]
(9.5.3)

From (9.5.2) and (9.5.3), we may conclude that $(\tilde{x} + \lambda \tilde{y}_2, \tilde{y} + \lambda \tilde{y}_2)$ is an equilibrium combination. Since $\lambda \mathbf{B} - \mathbf{A} \neq 0$, we find that this conclusion is contradictory with respect to the supposition that $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ is non-degenerated. Thus we may conclude that $(\mathbf{B} - \lambda \mathbf{A})$ is invertible.

In a similar manner, one may prove that $(\mathbf{B} - \lambda \mathbf{A})$ is invertible.

9.6 Definitions.

From proposition 9.4 we may conclude that all semi-equilibrium paths belonging to a non-degenerated equilibrium combination are determined by solutions $(x, u)$ of a system (9.3.2). For this reason, we now shall investigate system (9.3.2).

Every solution of (9.3.2) can be written as the sum of a particular solution of (9.3.2) and a solution $(x^0(t), u^0(t))$ of its homogeneous form:
\[
\begin{align*}
\mathbf{B} \dot{x}^0(t) + \mathbf{A} x^0(t) &= \tilde{z} \\
\mathbf{B} \dot{u}^0(t) + \mathbf{A} u^0(t) &= \tilde{v}
\end{align*}
\]
(9.6.1)
One may verify that:

\[
\begin{align*}
    \dot{\bar{x}}(t) &= \lambda t \bar{x}(t) \\
    \dot{\bar{u}}(t) &= \lambda t \bar{u}(t)
\end{align*}
\]  \hspace{1cm} (9.6.2)

is a particular solution of (9.3.2), \((\bar{x}, \bar{u}), (\bar{v}, \bar{v})\) being the non-degenerated equilibrium combination.

Now, we shall investigate system (9.6.1). First, we remark that it is everyday possible that none of the matrices \(A\) and \(B\) is invertible. However, the definition of a non-degenerated equilibrium combination implies (prop. 9.5) that the matrices \((B^{-1}A)\) and \((B^{-1}A)\) are both invertible.

Exploiting the fact that \((B^{-1}A)^{-1}\) exists, system (9.6.1) can be transformed into:

\[
\begin{align*}
    (B^{-1}A)^{-1} \dot{x}^0(t+1) &= (B^{-1}A)^{-1} \Delta x(t) \\
    B'(B^{-1}A)^{-1}(B^{-1}A')u^0(t) &= A'(B^{-1}A)^{-1}(B^{-1}A)u^0(t+1)
\end{align*}
\]  \hspace{1cm} (9.6.3)

When we define

\[
    H := (B^{-1}A)^{-1}B
\]  \hspace{1cm} (9.6.4)

which implies:

\[
    (B^{-1}A)^{-1}A = \frac{1}{\tau} (H-I)
\]  \hspace{1cm} (9.6.5)

then (9.6.3) can be reduced to:

\[
\begin{align*}
    \dot{x}^0(t+1) &= \frac{1}{\tau} (H-I)x^0(t) \\
    B'(B^{-1}A')u^0(t) &= \frac{1}{\tau} (H-I)'(B^{-1}A')u^0(t+1)
\end{align*}
\]  \hspace{1cm} (9.6.6)
Now, let $A$ be a lower Jordan matrix (3.132) of $H$, and $Q$ a corresponding non-singular complex matrix, such that $H = QAQ^{-1}$.

\[ H = QAQ^{-1} \quad (9.6.7) \]

Then, system (9.6.6) can be transformed into the following systems:

\[ A'z(t) = \frac{1}{n}(A-I)z(t), \quad t \geq 1 \tag{9.6.8} \]
\[ A'w(t) = \frac{1}{n}(A'-I)w(t+1), \quad t \geq 1 \tag{9.6.9} \]
\[ x^0(t) = Qz(t), \quad t \geq 1 \tag{9.6.10} \]
\[ (A'-A')u^0(t) = (Q^{-1})'w(t), \quad t \geq 1 \tag{9.6.11} \]

We observe that eigenvalues $\lambda_i$, column vectors of $Q$, and row vectors of $Q^{-1}$, with a non-zero imaginary part, always appear in pairs which are conjugate complex; i.e., a permutation matrix $S$ exists such that

\[ QS = \text{conj}(Q) := \Re(Q) - i \Im(Q) \]
\[ S^{-1} = \text{conj}(Q^{-1}) := \Re(Q^{-1}) - i \Im(Q^{-1}) \]
\[ S^{-1}A'S = \text{conj}(A') := \Re(A') - i \Im(A') \tag{9.6.12} \]

where $Q = \Re(Q) + i \Im(Q)$, $Q^{-1} = \Re(Q^{-1}) + i \Im(Q^{-1})$, and $A = \Re(A) + i \Im(A)$.

In the following theorems, solutions \(x^0(t), u^0(t)\) of (9.6.11) for which

\[ \left( \frac{d}{dt} x^0(t) = 0, \right. \quad t = -\infty \]
\[ \left. (\frac{d}{dt} u^0(t) = 0, \quad t = -\infty \right) \]

will play a central role.
In that context, it will be convenient to define:

- the spaces of $k$-dimensional complex vectors:

$$Z := \{ z | z \parallel_2 = 0, \text{ if } \lambda_{kk} = 0 \text{ or } \left| \frac{\lambda_{kk}^{-1}}{\lambda_{kk}} \right| \geq \delta \text{ for all } \delta \}$$ \hspace{1cm} (9.6.13)

$$W := \{ w | w \parallel_2 = 0, \text{ if } \lambda_{kk} = 1 \text{ or } \left| \frac{\lambda_{kk}^{-1}}{\lambda_{kk} - 1} \right| \geq 1 \}$$ \hspace{1cm} (9.6.14)

- the spaces of sequences of $k$-dimensional complex vectors:

$$Z := \left\{ \{z(t)\}_t^\infty \left| \frac{\Lambda z(t)}{\parallel z(t) \parallel_2} = \frac{1}{\pi} (\Lambda - \text{I}) z(t), \ t \geq 1 \right. \right\}$$ \hspace{1cm} (9.6.15)

$$W := \left\{ \{w(t)\}_t^\infty \left| \frac{\Lambda' w(t)}{\parallel w(t) \parallel_2} = \frac{1}{\pi} (\Lambda' - 1) w(t-1), \ t \geq 1 \right. \right\}$$ \hspace{1cm} (9.6.16)

- the spaces of $k$-dimensional real vectors:

$$X^0 := \{ x \in \mathbb{R}^k \left| x = qz, \text{ for some } z \in Z \right. \}$$ \hspace{1cm} (9.6.17)

$$U^0 := \{ u \in \mathbb{R}^k \left| u = (Q^{-1})^* w, \text{ for some } w \in W \right. \}$$ \hspace{1cm} (9.6.18)

- the subspaces of $\mathbb{R}^k$

$$X^0 := \left\{ \{x^0(t)\}_t^\infty \left| \frac{\Lambda x^0(t)}{\parallel x^0(t) \parallel_2} = \frac{1}{\pi} (\Lambda - \text{I}) x^0(t), \ t \geq 1 \right. \right\}$$ \hspace{1cm} (9.6.19)

$$U^0 := \left\{ \{u^0(t)\}_t^\infty \left| \frac{\Lambda u^0(t)}{\parallel u^0(t) \parallel_2} = \frac{1}{\pi} (\Lambda' - 1) u^0(t-1), \ t \geq 1 \right. \right\}$$ \hspace{1cm} (9.6.20)

- the subspaces of $\mathbb{R}^k$ and $\mathbb{R}^k$ (viz. def. 9.3-d):
\[ \dot{z}(t) = A(t)z(t) + B(t)u(t), \quad t \geq 0 \]

**9.7 Proposition.**

a) If a sequence of \( k \)-dimensional complex vectors \( \{x(t)\} \) satisfies (9.6.8), then:

\[ x_i(t) = 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 0. \]

b) If a sequence of \( k \)-dimensional complex vectors \( \{w(t)\} \) satisfies (9.6.9), then:

\[ w_i(t) = 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 1. \]

c) If \( \{x(t)\} \in \mathbb{Z} \), then:

\[ x(t) \in \mathbb{Z}, \quad t \geq 1, \]

i.e.: \( x_i(t) = 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 0 \) or \( \|x_i(t)/\lambda_{ii}\| \geq p_n. \)

d) If \( \{w(t)\} \in \mathbb{W} \), then:

\[ w(t) \in \mathbb{W}, \quad t \geq 1, \]

i.e.: \( w_i(t) = 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 1 \) or \( \|w_i(t)/\lambda_{ii}\| \geq 1. \)

e) If \( \bar{z} \in \mathbb{Z} \), then one and only one sequence \( \{z(t)\} \in \mathbb{Z} \) exists such that

\[ z(t) = \bar{z}. \]
i) If \( \overline{\omega} \in \nu \), then one and only one sequence \((\omega(t))_{t=0}^{\infty} \in \mu \) exists such that
\[
\nu(1) = \overline{\omega}.
\]
g) Positive numbers \( \frac{\delta}{\tau} < \rho \) and \( \alpha \) exist such that every
\((\omega(t))_{t=0}^{\infty} \in \overline{\omega} \) satisfies:
\[
I_{\omega}(t+\tau)_{t=0}^{\infty} \leq \sum_{k=1}^{\infty} \alpha_{k} I_{\omega}(t)_{t=0}^{\infty}, \quad t \geq 0, \quad \tau \geq 1.
\]
h) Positive numbers \( \frac{\delta}{\tau} < \tau \) and \( \alpha \) exist such that every
\((\omega(t))_{t=0}^{\infty} \in \overline{\omega} \) satisfies:
\[
I_{\omega}(t+\tau)_{t=0}^{\infty} \leq \sum_{k=1}^{\infty} \alpha_{k} I_{\omega}(t)_{t=0}^{\infty}, \quad t \geq 0, \quad \tau \geq 1.
\]

Proof.

(a) Suppose that \( \Lambda \) is diagonal. Then system (9.6.8) can be written
\[
\lambda_{11}z_{1}(t) = \frac{1}{\tau}\sum_{i=1}^{k} (\lambda_{ii}-1)z_{i}(t), \quad i=1, \ldots, k, \quad t \geq 1. \quad (9.7.1)
\]
Clearly, if \((z(t))_{t=0}^{\infty} \) satisfies (9.6.8), then:
\[
z_{1}(t) = 0, \quad t \geq 1, \quad \text{if } \lambda_{11} = 0. \quad (9.7.2)
\]
Suppose that \( \Lambda \), which is defined as a lower Jordan matrix, contains a Jordan block. Then the corresponding equalities of (9.6.8) may be written:
\[
\begin{align*}
\lambda_{11}z_{1}(t+1) & = \frac{1}{\tau}(\lambda_{11}-1)z_{1}(t) \\
z_{1}(t+1) & = \lambda_{12}z_{2}(t+1) + \frac{1}{\tau}z_{1}(t) + \frac{1}{\tau}(\lambda_{11}-1)z_{1+1}(t), \quad t \geq 1, \\
& \vdots \\
z_{1+j-1}(t+1) & = \lambda_{1+j}z_{j}(t+1) + \frac{1}{\tau}z_{1+j-1}(t) + \frac{1}{\tau}(\lambda_{11}-1)z_{1+j}, \quad j \geq 1.
\end{align*}
\]
where \( \lambda \) is the eigenvalue of the Jordan block.

Now, suppose that \( \lambda = 0 \). Then the first equality of (9.7.3) implies: 
\[
z_i(t) = 0, \quad t \geq 1.
\]
And so, by virtue of the second equality of (9.7.3): 
\[
z_{i+1}(t) = 0, \quad t \geq 1.
\]
Repeating this process, we find:
\[
\begin{align*}
z_i(t) &= 0, \quad t \geq 1, \\
z_{i+1}(t) &= 0, \quad t \geq 1.
\end{align*}
\]
Hence we may conclude that also in case \( \Lambda \) is not diagonal, the equalities hold.

(b) This property can be proved in a similar manner as 9.7-a.

(c) We first assume that \( \Lambda \) is diagonal. Then (9.7.1) and (9.7.2) imply that (9.6.8) can be written:
\[
\begin{align*}
\frac{1}{\rho} \int_{-1}^{t} z_i(t) &\, dt = \\
\frac{\lambda_{ii}^{-1}}{\rho \lambda_{ii}} (t) z_i(t) &\, dt = \\
z_i(t) &= 0, \quad \text{if } \lambda_{ii} = 0,
\end{align*}
\]
Clearly, \( \frac{1}{\rho} \int_{-1}^{0} z_i(t) &\, dt = 0, \quad t = \infty \), implies
\[
z_i(t) = 0, \quad t \geq 1, \quad \text{if } \lambda_{ii} = 0 \text{ or } \left| \frac{\lambda_{ii}^{-1}}{\rho \lambda_{ii}} \right| \geq \rho \nu.
\]

In connection with the definitions (9.6.13) and (9.6.15), we may conclude that \( (z(t))^{\infty} \in \mathcal{I} \) implies \( z(t) \in \mathcal{I}, \quad t \geq 1, \) in case \( \Lambda \) is diagonal. In the case that \( \Lambda \) is not diagonal, the validity of this property can be proved in a similar manner as done for 9.7-a.

(d) This property can be proved in a similar manner as 9.7-c.

(e) First we observe that for every vector \( z^1 \in \mathcal{I} \) a unique vector \( z^2 \in \mathcal{I} \) exists such that: 
\[ A z^2 = \frac{1}{n} (L-1) z^1. \]  \hspace{1cm} (9.7.4) 

This implies that for every \( z(\cdot) \in Z \) a unique sequence 
\[ \{ z(t) \}_{t=1}^{\infty} \] exists such that
\[ \begin{align*}
A z(t+1) &= \frac{1}{n} (L-1) z(t), \quad t \geq 1, \\
z(t+1) &\in Z
\end{align*} \hspace{1cm} (9.7.5) \]

When we define the matrix \( \Lambda \) by:
\[ \begin{align*}
\lambda_{ij} &= \lambda_{ij}, \quad i,j=1,...,k, \quad i \neq j \\
\lambda_{ii} &= \lambda_{ii}, \text{ if } \lambda_{ii} \neq 0, \text{ and } \left| \frac{\lambda_{ii} - 1}{\lambda_{ii}} \right| < 0 \pi \\
\lambda_{ii} &= 1, \text{ in the other case}
\end{align*} \hspace{1cm} (9.7.6) \]

and the matrix \( \hat{\Lambda} \) by:
\[ \hat{\Lambda} := \frac{1}{2} \Lambda^{-1} (\Lambda - 1), \hspace{1cm} (9.7.7) \]
(note: matrix \( \hat{\Lambda} \) is invertible), then the definition of \( Z \).

(9.6.13) implies that (9.7.5) can be written:
\[ z(t+1) = \hat{\Lambda} z(t), \quad t \geq 0, \quad z(1) \in Z. \hspace{1cm} (9.7.8) \]

One may verify that \( \hat{\Lambda} \) is triangular with diagonal elements:
\[ \begin{align*}
\hat{\lambda}_{ii} &= \frac{1}{2} \left| \frac{\lambda_{ii} - 1}{\lambda_{ii}} \right|, \text{ if } \lambda_{ii} \neq 0 \text{ and } \left| \frac{\lambda_{ii} - 1}{\lambda_{ii}} \right| < 0 \pi \\
\hat{\lambda}_{ii} &= 0, \text{ in the other case}
\end{align*} \hspace{1cm} (9.7.9) \]

This implies that the \( \hat{\lambda}_{ii} \) in (9.7.9) are the eigenvalues of \( \hat{\Lambda} \), so that:
\[ \bar{\lambda} := \max_i |\hat{\lambda}_{ii}| < \infty. \]
Since (*) for all \( \delta > 0 \) a number \( N_\delta \) exists for which

\[
1_{N_\delta}^T t \leq N_\delta (T + 5)^t, \quad t \geq 0,
\]

we may conclude that numbers \( \frac{1}{N_\delta} \in [0,1] \) and \( N_1 > 0 \) exist such that every sequence \( \{ z(t) \} \_1 \) which satisfies (9.7.5) also satisfies

\[
1_{z(t+T)} \leq \frac{1}{N_1} 1_{z(t)} 1_{-1}, \quad t \geq 0, \quad T \geq 1.
\]

Since \( \frac{1}{N_\delta} \in [0,1] \), this implies:

\[
(1_{N_\delta})^T z(t) = 0, \quad t = \infty. \tag{9.7.11}
\]

From (9.7.5), (9.7.11), and from the definition of \( g \) (9.6.15), we may conclude: \( \{ z(t) \}_1 \in g \). Since (9.7.8) implies the uniqueness of \( \{ z(t) \}_1 \), given \( z(1) \), we may conclude that 9.7-6 has been proved.

(g) Since every \( \{ z(t) \}_1 \) satisfies (9.7.6), this property is implied by (9.7.10).

(f) and (h): These properties can be proved in a similar manner as 9.7-6 and 9.7-8.

9.8 Proposition.

a) If a sequence of \( k \)-dimensional real vectors \( \{ z^0(t) \}_1 \) satisfies

\[
R^0 z^0(t+1) = A z^0(t), \quad t \geq 1,
\]

then the sequence \( \{ z(t) \} \_1 \) defined by (9.6.10) satisfies:

\[
z_1(t) = 0, \quad t \geq 1, \quad \text{if } \lambda_{11} = 0.
\]

b) If a sequence of \( k \)-dimensional real vectors \( \{ u^0(t) \}_1 \) satisfies

\[
R^0 u^0(t+1) = A u^0(t), \quad t \geq 1,
\]

then the sequence \( \{ w(t) \} \_1 \) defined by (9.6.11) satisfies:

\[
(*) \text{ This well-known property can easily be proved by combining the theorems 2.2.8 and 2.2.1 of Ortega and Rheinboldt (7).}
\]
\( w_i(t) = 0, \ t \geq 1, \) if \( \lambda_{ii} = 1. \)

c) If \( \{x^0(t)\}_1^m \in X^0, \) then
\[
x^0(t) \in X^0, \ t \geq 1.
\]
d) If \( \{u^0(t)\}_1^m \in U^0, \) then
\[
(\tilde{A}' - \eta A')u^0(t) \in U^0, \ t \geq 1.
\]
e) If \( \bar{x} \in X^0, \) then one and only one sequence \( \{x^0(t)\}_1^m \in X^0 \)
exists such that
\[
x^0(t) = \bar{x}.
\]
f) If \( \bar{u} \) satisfies \( (\tilde{A}' - \eta A')\bar{u} \in U^0, \) then one and only one
sequence \( \{u^0(t)\}_1^m \in U^0 \) exists such that
\[
u^0(t) = \bar{u}.
\]
g) For every \( \varepsilon > 0 \) a period \( T_{\varepsilon} \geq 1 \) exists such that every
\( \{(x(t))_1^m, (y(t))_1^m\} \in XX \) satisfies:
\[
\| \left( \frac{1}{\varepsilon} \right)^T (x(t), y(t)) - (\bar{x}, \bar{y}) \| \leq \varepsilon \left( \frac{1}{\varepsilon} \right) (x(t), y(t)) - (\bar{x}, \bar{y}) \|, \quad t \geq 1, \ T \geq T_{\varepsilon}.
\]
h) For every \( \varepsilon > 0 \) a period \( T_{\varepsilon} \geq 1 \) exists such that every
\( \{(u(t))_1^m, (v(t))_1^m\} \in YY \) satisfies:
\[
\| \left( \frac{1}{\varepsilon} \right)^T (u(t), v(t)) - (\bar{u}, \bar{v}) \| \leq \varepsilon \left( \frac{1}{\varepsilon} \right) (u(t), v(t)) - (\bar{u}, \bar{v}) \|, \quad t \geq 1, \ T \geq T_{\varepsilon}.
\]
i) A positive number \( \delta \) exists such that every
\( \{(x(t))_1^m, (y(t))_1^m\} \in XX \) satisfying
1 \( y(T) \leq \delta_1 \), for some \( T \geq 1 \),

also satisfies:

\( x(t), y(t) \geq 0, t \geq T+1 \).

j) A positive number \( \delta_2 \) exists such that every \((\{ u(t) \}, \{ v(t) \}) \in \mathbb{R}^2 \) satisfying

\( 1 \left( \begin{array}{c} 1 \\ \frac{1}{2} \end{array} \right)^T \alpha(T) - \beta \right) \leq \delta_2 \), for some \( T \geq 1 \),

also satisfies:

\( u(t), v(t) \geq 0, t \geq T \).

Proof.

(a) If \( \{ x^0(t) \} \) satisfies \( \Delta x(t+1) = \Delta x(t), t \geq 1 \), then the sequence \( \{ x(t) \} \) defined by (9.6.10) satisfies (9.6.8).

By virtue of proposition 9.7-a, this implies the validity of 9.8-a.

(b) With the help of 9.7-b, this property can be proved in a similar manner.

(c) If \( \{ x^0(t) \} \) satisfies \( \{ x^0(t) \} \) defined by \( x^0(t) = Q x(t), t \geq 1 \), satisfies:

\( 1 \left( \begin{array}{c} 1 \\ \frac{1}{2} \end{array} \right)^T x(t+1) \geq 0, t = \infty \).

Since \( Q \) is invertible, the corresponding sequence \( \{ x(t) \} \) defined by \( x(t) = Q x(t), t \geq 1 \), satisfies:

\( 1 \left( \begin{array}{c} 1 \\ \frac{1}{2} \end{array} \right)^T x(t+1) \geq 0, t = \infty \).

Since \( \{ x(t) \} \) satisfies (9.6.8), this implies (viz. proposition 9.7-c) that \( x(t) \in Z, t \geq 1 \), and successively (viz. def. 9.6.17): \( x^0(t) \in Z^0, t \geq 1 \).

(d) This property can be proved in a similar manner as 9.8-c.
(e) Firstly, we observe that \( QS = \text{conj}(Q) \) (viz. 9.8.12) implies the equivalence of the following equalities:

\[
\text{conj}(Qz) = Qz, \tag{9.8.1}
\]

\[
S^{-1}z = \text{conj}(z), \tag{9.8.2}
\]

for \( Qz = QS^{-1}z = \text{conj}(Q)(S^{-1}z) \) and \( \text{conj}(Qz) = \text{conj}(Q)\text{conj}(z) \); which implies the equivalence.

Secondly, we observe that \( S^{-1}A \ A = \text{conj}(A) \) implies:

\[
S^{-1}A S = \text{conj}(A), \tag{9.8.3}
\]

\( A \) being the matrix defined by (9.7.7). For \( S^{-1}A S = \text{conj}(A) \) and definition (9.7.6) imply: \( (S^{-1}A S) = \text{conj}(A) \), so that:

\[
1 = (S^{-1}A^{-1}S)(S^{-1}A S) = (S^{-1}A^{-1})\text{conj}(A). \tag{9.8.4}
\]

Since \( \text{conj}(A^{-1})\text{conj}(A) = 1 \), the latter implies: \( (S^{-1}A S) = \text{conj}(A^{-1}) \) and so (viz. def. 9.7.7) the equality (9.8.3), as well.

Now, let \( \bar{x} \in X^S \), so that (viz. def. 9.6.17) there is a unique \( \bar{z} \in Z \), \( Q\bar{z} = \bar{x} \). This implies (proposition 9.7-e) the existence of a unique sequence \( (z(t))_0 \in Z \), with \( z(1) = \bar{z} \). Since this sequence also (proposition 9.7-e) satisfies \( z(t) \in Z \), \( t \geq 1 \), and since the systems (9.7.5) and (9.7.8) are equivalent, we may conclude:

\[
z(t+1) = \bar{z}z(t), \quad t \geq 1. \tag{9.8.4}
\]

Since \( \text{Im}(Q\bar{z}) = 0 \) implies (viz. 9.8.1 and 9.8.2) that \( S^{-1}z = \text{conj}(z) \), we may conclude by deduction (9.8.3 and 9.8.4):

\[
S^{-1}z(t) = \text{conj}(z(t)), \quad t \geq 1.
\]

By virtue of the equivalence of (9.8.1) and (9.8.2), this implies: \( \text{conj}(Qz(t)) = Qz(t), \quad t \geq 1 \). Thus, we may conclude that \( (x^S(t))_0 \), defined by
\[ x^0(t) := Qx(t), \quad t \geq 1, \]  
(9.8.3)

is a sequence of real \( k \)-dimensional vectors. The equalities (9.6.7), (9.6.8), and (9.6.10) imply that \( (x^0(t))_{i}^{m} \) satisfies

\[ \Delta x(t) = \Delta x(t), \quad t \geq 1. \]

Moreover, since \( (x(t))_{1}^{m} \in \mathbb{X} \) (viz. def. 9.6.15), this sequence converges in the following manner

\[ (\frac{1}{p})^{t} x^0(t) \to 0, \quad t \to \infty. \]
(9.8.5)

From (9.8.5) and (9.8.6) we may conclude that \( (x^0(t))_{i}^{m} \in \mathbb{X}. \)

Since \( \overline{X} = QX(1) \) and (9.8.5) implies \( x^0(1) = \overline{X} \), and since \( (z(t))_{2}^{m} \) is unique, we may state that 9.8-e is proved.

(f) This property can be proved in a similar manner as 9.8-e.

(g) and (i) For every \( (\{x(t)\}_{i}^{m}, \{y(t)\}_{i}^{m}) \in \mathbb{X} \), a sequence \( (x(t))_{i}^{m} \in \mathbb{X} \) exists such that

\[ (x(t) - T^0_0) = SpQz(t), \quad t \geq 1. \]

With the help of 9.7-g, we may conclude that numbers \( \tilde{X} \in [0,1] \) and \( N, \) exist such that

\[ x(t) = T^0_0 x(t) - T^0_0 x(t) - T^0_0 x(t), \quad t \geq 0, T \geq 1, \]
(9.8.7)

for all \( (\{x(t)\}_{i}^{m}, \{y(t)\}_{i}^{m}) \in \mathbb{X} \). We write (9.8.7) in the form:

\[ (\frac{1}{p})^{t} x(t) - T^0_0 x(t) - T^0_0 x(t), \quad t \geq 0, T \geq 1, \]
(9.8.8)

where \( N = \#SpQz(N), x^0 = \#SpQz. \)

Since every \( (\{x(t)\}_{i}^{m}, \{y(t)\}_{i}^{m}) \in \mathbb{X} \) satisfies
we may conclude

$$I \left( \frac{1}{\rho} \right)^{t+1} y(t) - \tilde{y}_\omega \leq \|B\| I \left( \frac{1}{\rho} \right)^{t+1} x(t-1) - \tilde{x}_\omega,$$

and successively:

$$I \left( \frac{1}{\rho} \right)^{t+1} \left( x(t-1), y(t-1) \right) - (\tilde{x}, \tilde{y}) \leq (1 + \|B\|) I \left( \frac{1}{\rho} \right)^{t+1} x(t-1) - \tilde{x}_\omega,$$

Combining (9.8.8) and (9.8.9), we may conclude that, for $M_2 := (1 + \|B\|) I \left( \frac{1}{\rho} \right)^{t+1} M_1$, all $\left( \left( x(t) \right), \left( y(t) \right) \right) \in \tilde{X}$ satisfy:

$$I \left( \frac{1}{\rho} \right)^{t+1} \left( x(t), y(t) \right) - (\tilde{x}, \tilde{y}) \leq M_2 I \left( \frac{1}{\rho} \right)^{t+1} x(t) - \tilde{x}_\omega,$$

where $\left( \frac{1}{\rho} \right) \in (0, 1)$. Since $\left( \frac{1}{\rho} \right) \in (0, 1)$, for every $\varepsilon > 0$ a period $T_\varepsilon$ exists such that

$$\left( \frac{1}{\rho} \right)^{T_\varepsilon} \leq \varepsilon, \quad T \geq T_\varepsilon.$$

From (9.8.10) and (9.8.11) we may conclude

$$\|I \left( \frac{1}{\rho} \right)^{t+1} (x(t), y(t)) - (\tilde{x}, \tilde{y})\|_\omega \leq \varepsilon I \left( \frac{1}{\rho} \right)^{t+1} (x(t), y(t)) - (\tilde{x}, \tilde{y})\|_\omega,$$

This proves property 9.8-2. Property 9.8-1 can be proved by defining the positive number

$$\delta_1 := \frac{1}{M_2} \min \left( \tilde{\tilde{x}}_\omega, \tilde{\tilde{y}}_\omega \right) \quad \tilde{\tilde{x}}_\omega > 0, \quad \tilde{\tilde{y}}_\omega > 0.$$
so that we may conclude from (9.8.10) and from the definition 
(9.6.2) of $\vec{x}\vec{y}$, that

$$f \left( \frac{1}{\rho} \right)^T \vec{x}(T) \vec{y} \leq \delta$$

implies:

$$f \left( \frac{1}{\rho} \right)^T (\vec{x}(t+T), \vec{y}(t+T)) \cdot (\vec{x}, \vec{y}) \leq$$

$$\leq \min \{ x_j, y_j \} \cdot \delta$$

This implies the validity of property 9.8-i.

(h) and (j) These properties may be proved in a similar manner

as 9.8-g,i.

9.9 Theorem.

For every pair of semi equilibrium paths $((x,y),(u,v))$ and

$((\vec{x},\vec{y}),(\vec{u},\vec{v}))$, belonging to a non-degenerated equilibrium com-

bination, the following properties hold:

(a) If, for some $T \geq 0$:

$$(x(T),y(T)) = (\vec{x}(T),\vec{y}(T)),$$  \hspace{1cm} (9.9.1)

then:

$$(x(t),y(t)) = (\vec{x}(T),\vec{y}(T)), \hspace{1cm} t \geq T.$$  \hspace{1cm} (9.9.2)

(b) If, for some $T \geq 0$:

$$(x(T),y(T)) = (\vec{x}(T),\vec{y}(T)),$$  \hspace{1cm} (9.9.3)

then:

$$(u(t),v(t)) = (\vec{u}(T),\vec{v}(T)), \hspace{1cm} t \geq T.$$  \hspace{1cm} (9.9.4)
Proof.

Let \((x, y)\) and \((\bar{x}, \bar{y})\) be the primal parts of semi equilibrium paths belonging to a non-degenerated equilibrium combination \((\bar{x}, \bar{y}), (\bar{u}, \bar{v})\). Then we define:

\[
x^0(t) := \text{Sp}(x(c) - \bar{y}(t)), \quad t \geq 1.
\]  

(9.9.5)

Then it follows from proposition 9.4-b that

\[
x^0(t + 1) = Ax^0(t), \quad t \geq 1.
\]

This implies, by virtue of proposition 9.8-a, the existence of a sequence \(\{z(t)\}_t\) satisfying

\[
x^0(t) = Qz(t), \quad t \geq 1,
\]  

(9.9.6)

\[
Ax(t + 1) = \frac{1}{\lambda}(\lambda - I)z(t), \quad t \geq 1,
\]  

(9.9.7)

\[
z_i(t) = 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 0.
\]  

(9.9.8)

Now suppose that \((x(T), y(T)) = (\bar{x}(T), \bar{y}(T))\) for some \(T \geq 1\). Then, (9.9.5) and (9.9.6) imply \(z(T) = 0\), and so, by virtue of (9.9.7):

\[
z_i(t) = 0, \quad t \geq T, \text{ if } \lambda_{ii} \neq 0.
\]  

(9.9.9)

Clearly, (9.9.8) and (9.9.9) imply: \(z(t) = 0, \quad t \geq T\), and so, in connection with (9.9.6) and (9.9.5), we may conclude: \((x(t), y(t)) = (\bar{x}(t), \bar{y}(t)), \quad t \geq T\).

The b) part of the theorem can be proved in a similar manner.

9.10 Remark.

In theorem 9.2 we have found that all consistent semi equilibrium paths \(((x, y), (u, v))\) of an LP-problem (P- or D-directed; exponential; virtually superregular) satisfy:
\( (x_1/\rho, y/\rho) \in \mathbb{R}^n \times \mathbb{R}^m \)  \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} (9.10.1) \\
\( (u_1/\tau, v/\tau) \in \mathbb{R}^n \times \mathbb{R}^m \).

Using the definitions (9.6.3) to (9.6.11), one can derive that, for every consistent semi equilibrium path \((x, y), (u, v)\) belonging to a non-degenerated equilibrium combination \((\mathbf{x}, \mathbf{y}), (\mathbf{u}, \mathbf{v})\), sequences of complex vectors \(\{z(t)\}_1^\infty\) and \(\{\omega(t)\}_1^\infty\) exist such that

\[
\begin{align*}
x(t) &= \text{SpQz}(t), \quad t \geq 1, \\
L^2z(t) &= \frac{1}{n}(\Lambda - I)z(t), \quad t \geq 1, \\
(L^* - \nu^* \Lambda^*) \omega(t) &= (Q^{-1})^* \omega(t), \quad t \geq 1, \\
\Lambda^2\omega(t) &= \frac{1}{n}(\Lambda - I)\omega(t+1), \quad t \geq 0.
\end{align*}
\]

Moreover, proposition 9.8-a,b implies:

\[
\begin{align*}
z_i(t) &= 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 0, \\
\omega_i(t) &= 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 1.
\end{align*}
\]

Since (9.10.1), (9.10.2), and (9.10.4) imply

\[
\| \frac{1}{n}z(t) \|_\infty \leq M_1, \quad t \geq 1, \text{ for some } M_1, \\
\| \frac{1}{n}u(t) \|_\infty \leq M_2, \quad t \geq 1, \text{ for some } M_2,
\]

one can derive from (9.10.3), (9.10.6), and from (9.10.5), (9.10.7):

\[
\begin{align*}
z_i(t) &= 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 0 \text{ or } |(\lambda_{ii}^{-1})/\lambda_{ii}| > \rho, \\
\omega_i(t) &= 0, \quad t \geq 1, \text{ if } \lambda_{ii} = 1 \text{ or } |(\lambda_{ii}^{-1})/\lambda_{ii}| > 1.
\end{align*}
\]

Thus we may conclude that for every consistent semi equilibrium path belonging to a non-degenerated equilibrium combination \((\mathbf{x}, \mathbf{y}), (\mathbf{u}, \mathbf{v})\) (\(\mathbf{x}\) possessing at least one positive component), sequences of complex vectors \(\{z(t)\}_1^\infty\) and \(\{\omega(t)\}_1^\infty\) exist, satisfying (9.10.2), (9.10.3), (9.10.8) and (9.10.5), (9.10.9).
This means that, if there are no eigenvalues \( \lambda_{11} \) for which 

\[
|\frac{(\lambda_{11} - 1)}{\lambda_{11}}| \text{ is equal to } 0 \text{ or to one},
\]

then such sequences \( \{x(t)\}_{t=0}^{\infty} \) and \( \{u(t)\}_{t=0}^{\infty} \) (viz. proposition 9.7-a, f, and definitions 9.6.13 to 9.6.16) satisfy

\[
\left(\frac{1}{\partial t}\right)^t x(t) \to 0, \ t \to \infty,
\]

\[
\left(\frac{1}{\partial t}\right)^t u(t) \to 0, \ t \to \infty,
\]

which implies:

\[
\left(\frac{1}{\partial t}\right)^t (x(t), y(t)) = (x, y), \ t \to \infty,
\]

\[
\left(\frac{1}{\partial t}\right)^t (u(t), v(t)) = (u, v), \ t \to \infty.
\]

Hence we may conclude: If \( H := (E' - A')^{-1} B \) has no eigenvalues 

\( \lambda_{11} \) for which 

\[
|\frac{(\lambda_{11} - 1)}{\lambda_{11}}| \text{ is equal to } 0 \text{ or to one},
\]

then all consistent semi equilibrium paths converge in the sense of (9.10.10).

9.11 Definition.

In the next theorem an LP-problem (P- or D-directed; \( f(t) = \tilde{f}, \ p(t) = \tilde{p}, \ t \geq K \); superregular) will be considered. A corresponding LP-problem \( f(t) = \tilde{f}, \ p(t) = \tilde{p}, \ t \geq K \) will be called the associated exponential LP-problem.

We observe that, if the original problem is P- or D-directed and virtually superregular, then an associated exponential LP-problem is P- or D-directed and virtually superregular, as well.

A combination of vectors \((\tilde{x}, \tilde{y})\), \((\tilde{u}, \tilde{v})\) is called an equilibrium combination of an LP-problem \( f(t) = \tilde{f}, \ p(t) = \tilde{p}, \ t \geq K \) if it is an equilibrium combination of the associated exponential LP-problem.
9.12 Theorem.

If \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) is an equilibrium combination of an LP-problem \((P^-)\) or \(P^-\) directed; \(f(t) = \tilde{y}, p(t) = \tilde{y}, t \in \mathbb{R};\) superregular), which satisfies the following conditions:

a) \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) is non-degenerated,

b) Every consistent semi-equilibrium path \(((x,y),(v,v))\) of the associated exponential LP-problem, belonging to this equilibrium combination converges in the following manner:

\[
\begin{align*}
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = 0 \\
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = \infty
\end{align*}
\]  

(9.12.1)

c) The associated exponential LP-problem is regular, for the initial vector \(x(0) := \tilde{x},\)

then the following properties hold:

d) A period \(T\) exists such that for all optimal solutions \(((x,y),(u,v))\) of the original LP-problem:

\[
\begin{align*}
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = T \\
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = 2T
\end{align*}
\]  

(9.12.2)

\[
\begin{align*}
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = T \\
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = 2T
\end{align*}
\]  

(9.12.3)

e) All optimal solutions \(((x,y),(u,v))\) of the original problem converge in the following manner:

\[
\begin{align*}
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = 0 \\
\left(\begin{array}{c}
\frac{1}{T}L(x(t),y(t)) + (\tilde{x}, \tilde{y}) \\
\frac{1}{T}L(u(t),v(t)) + (\tilde{u}, \tilde{v})
\end{array}\right), & \quad t = \infty
\end{align*}
\]  

(9.12.4)

(9.12.5)

Proof.

Let \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) be an equilibrium combination which satisfies the conditions a, b, and c.
Define the sets $F^0 \subseteq I_n^0$ and $F \subseteq I_n^0$ as follows:

\[ F^0 := \{ g^0 \mid g^0 := \lambda(1-\lambda)(\xi^1, \xi^2, \ldots, \xi^m)' \mid \lambda \in [0,1] \} \]
\[ F := \{ q \mid q := \lambda p + (1-\lambda)(\bar{g}^0, \bar{g}^1, \ldots, \bar{g}^m)' \mid \lambda \in [0,1] \} \]

(9.12.6)

This definition implies that $F^0$ and $F$ are closed and bounded sets in $l^0$-dimensional subspaces of $I_n^0$ and $I_n^0$. This implies the following property:

1) $F^0$ and $F$ are compact.

Now we consider, for each vector $(g^0, q) \in F^0 \times F$ the following LP-problem,

\[
\begin{align*}
\sup \langle q, x \rangle = g^0 \\
\text{s.t.} & \quad \begin{bmatrix} G^1 & 0 \end{bmatrix} x = g^0 \\
& \quad \begin{bmatrix} 1 & 0 \end{bmatrix} y \leq 1 \quad \forall y \in I_n^1 \\
\end{align*}
\]

\[
\inf \langle g^0, u \rangle = q \\
\text{s.t.} & \quad \begin{bmatrix} G^1 & 0 \end{bmatrix} u = q \\
& \quad \begin{bmatrix} 1 & 0 \end{bmatrix} v \leq 1 \quad \forall v \in I_n^1
\]

(9.12.7)

where $G$ is the matrix (def. 6.2.1) of the original problem.

For every $(g^0, q) \in F^0 \times F$, the set of $l^0$-transforms of primal optimal solutions is denoted by $\Sigma Y(g^0, q)$, and the set of $l^1$-transforms of dual optimal solutions by $\Sigma U(g^0, q)$.

Since the original problem is $P$- or $D$-directed and superregular, and since the associated exponential LP-problem is regular, the following properties hold:

2) For every $(g^0, q) \in F^0 \times F$: the LP-problem (9.12.7) is $P$- or $D$-directed and strong regular.

3) For every $(g^0, q) \in F^0 \times F$ (property 1, property 2, and theorem 7.3)

\[ \Sigma Y(g^0, q) \neq \emptyset \]
\[ \Sigma U(g^0, q) \neq \emptyset \]
4) Numbers $M_1$ and $M_2$ exist (property 1, property 2, and theorem 7.3) such that:

\[
\tilde{\tilde{XY}}(\tilde{P}^0xP) \subset \sigma_m^\infty(M_1) \times \sigma_m^\infty(M_1),
\]

\[
\tilde{\tilde{UV}}(\tilde{P}^0xP) \subset \sigma_m^\infty(M_2) \times \sigma_m^\infty(M_2).
\]

5) For every $(g^0,q) \in P^0xP$ (property 2 and theorem 6.19):

\[
<v,x,y> = <u,y> = 0, (x,y) \in \tilde{\tilde{XY}}(g^0,q), (u,v) \in \tilde{\tilde{UV}}(g^0,q).
\]

6) For every $(g^0,q) \in P^0xP$ and every number $\alpha > 0$, neighborhoods $\Omega(g^0,q;\alpha) \subset \bigcap_{m=1}^n (g^0,q)$ of $(g^0,q)$ exist (property 1, property 2, and theorem 7.5) such that:

\[
\tilde{\tilde{XY}}(g^0,q) \cap (\text{int}(\sigma_m^\infty(\Omega))) \supset \tilde{\tilde{XY}}(\Omega(g^0,q;\alpha) \cap (P^0xP)).
\]

\[
\tilde{\tilde{UV}}(g^0,q) \cap (\text{int}(\sigma_m^\infty(\Omega))) \supset \tilde{\tilde{UV}}(\Omega(g^0,q;\alpha) \cap (P^0xP)).
\]

7) If $(x,y, (u,v)) \in \tilde{\tilde{XY}}(P^0xP) \times \tilde{\tilde{UV}}(P^0xP)$ satisfies

\[
(x,y)'(x(t),y(t)) = 0 \quad t \geq L, \quad \text{for some } L \geq K, \quad (9.12.8)
\]

(K being the period for which $f(t) = \tilde{f}, \tilde{p}(t) = \tilde{\tilde{P}}, t \geq K$), then:

\[
(x(t),y(t)) = (\tilde{x}, \tilde{y}), \quad t = \omega,
\]

\[
(u(t),v(t)) = (\tilde{u}, \tilde{v}), \quad t = \omega.
\]

For

\[
((\text{ex}(t-L)_{L=1}^\infty), (\text{ey}(t-L)_{L=1}^\infty), ((\text{eu}(t-L)_{L=1}^\infty), (\text{ev}(t-L)_{L=1}^\infty))
\]

is a semi equilibrium path of the associated exponential LP-problem with the initial vector $x(0) = x(L)$. Hence, condition b) implies this property.
8) For every $\varepsilon > 0$ a period $\tau_{\varepsilon}$ exists, such that all vectors $(x(t), y(t)) \in X \times Y$ which satisfy (9.12.8), also (proposition 9.8.a.b and property 7) satisfy:

\[
\|x(t+\tau_{\varepsilon}) - (x_{0}, y_{0})\|_{m} \leq \varepsilon \|x(t), y(t)\|_{m} \quad t \geq \tau_{\varepsilon},
\]

\[
\|u(t+\tau_{\varepsilon}), v(t+\tau_{\varepsilon})\|_{m} \leq \varepsilon \|u(t), v(t)\|_{m} \quad t \geq \tau_{\varepsilon}.
\]

9) For every $\alpha > 0$ a period $\tau_{\alpha}$ exists, such that all vectors $(u(t), v(t)) \in X \times Y$ which satisfy (9.12.8), also satisfy:

\[
\|x(t), y(t)\|_{m} \leq \alpha \quad t \geq \tau_{\alpha}, \quad (9.12.9)
\]

For property 4) implies:

\[
\|x(t), y(t)\|_{m} \leq M_{1} \|x, y\|_{m}, \quad (3.12.10)
\]

\[
\|u(t), v(t)\|_{m} \leq M_{2} \|u, v\|_{m}, \quad (3.12.10)
\]

and so, when we choose the positive number $\varepsilon$ of property 8) in such a manner that

\[
\varepsilon \left( M_{1} \|x, y\|_{m} \right) < \alpha
\]

\[
\varepsilon \left( M_{2} \|u, v\|_{m} \right) < \alpha
\]

it appears that property 9) is implicated by (9.12.10) and property 8).

Now we choose the positive number $\alpha$ of property 5 and property 9, as follows:

\[
\alpha := \min \left( \min_{j} \left( x_{j} \right), \left( x_{j} \right) > 0 \right), \min \left( \min_{j} \left( y_{j} \right), \left( y_{j} \right) > 0 \right)
\]

\[
(9.12.11)
\]
This definition implies the validity of the next property:

10) If, for some \((\hat{g}, q) \in F^0 \times \mathbb{P}\), a vector \\
\((x,y),(x,y)\) \(\in \tilde{X}_{\tilde{X}}(\hat{g}, q) \times \tilde{V}_{\tilde{V}}(\hat{g}, q)\) and a period \(S \geq \delta\) exist, \\
such that \\
\[
\begin{align*}
&\|(x(t), y(t)) - (\hat{x}, \hat{y})\|_\infty \leq 3\delta \\
&\|(u(t), v(t)) - (\hat{u}, \hat{v})\|_\infty \leq 3\delta
\end{align*}
\]
\(t \geq S\), \(9.12.12\)

then, all vectors \((x,y)(u,v)\) \(\in \tilde{X}_{\tilde{X}}(\hat{g}, q) \times \tilde{V}_{\tilde{V}}(\hat{g}, q)\) satisfy:
\[
\begin{align*}
(\hat{x}, \hat{y})' (x(t), y(t)) &= 0 \\
(\hat{u}, \hat{v})' (u(t), v(t)) &= 0
\end{align*}
\(t \geq S\), \(9.12.13\)

For \((9.12.11)\) and \((9.12.12)\) imply:
\[
\begin{align*}
(x(t), y(t)) &\geq i(\hat{x}, \hat{y}) \\
(u(t), v(t)) &\geq i(\hat{u}, \hat{v})
\end{align*}
\(t \geq S\), \(9.12.14\)

and so, since \((\hat{x}, \hat{y}), (\hat{u}, \hat{v})\) is non-degenerated (def. 9.1), \\
property 10 is implied by \((9.12.14)\) and property 5.

Now, consider the neighbourhoods \(N(\hat{g}, q; \delta)\) of proposition 6, in \\
which \(\delta\) is defined by \((9.12.11)\). Since the sets \(F^0\) and \(\mathbb{P}\) are \\
compact (prop. 1), the following property holds (Heine-Borel):

11) A finite number of vectors \\
\((\hat{g}^1, q^1), (\hat{g}^2, q^2), \ldots, (\hat{g}^k, q^k) \in F^0 \times \mathbb{P}\) exists such that:
\[
\bigcup_{i=1}^{k} \mathbb{N}(\hat{g}^i, q^i; \delta) \supset F^0 \times \mathbb{P}.
\]
\(9.12.15\)

Moreover, we may choose these vectors in such a manner \\
(def. 9.12.6) that:
From (9.12.16) and from property 6 we may conclude:

(2) For every pair \( (g_i^i, q_i^i), (g_{i+1}^i, q_{i+1}^i) \), vectors

\[
((x_i^i, y_i^i), (u_i^i, v_i^i)) \in X Y(g_i^i, q_i^i) \times UV(g_i^i, q_i^i),
\]

\[
((x_{i+1}^i, y_{i+1}^i), (u_{i+1}^i, v_{i+1}^i)) \in X Y(g_{i+1}^i, q_{i+1}^i) \times UV(g_{i+1}^i, q_{i+1}^i)
\]

exist, such that

\[
\begin{align*}
\|x_{i+1}^i &- x_i^i\|_\infty < 2a \\
\|u_{i+1}^i &- u_i^i\|_\infty < 2a
\end{align*}
\]

(3) If all vectors \( ((x, y), (u, v)) \in X Y(g_i^i, q_i^i) \times UV(g_i^i, q_i^i), i < k \) satisfy:

\[
\begin{align*}
(\dot{x}, \dot{y})' (x(t), y(t)) &= 0 \\
(\dot{y}, \dot{u})' (u(t), v(t)) &= 0
\end{align*}
\]  \( t \geq L \),

(9.12.17)

for some fixed period \( L \geq K \), then all vectors

\( ((x, y), (u, v)) \in X Y(g_i^i, q_i^i) \times UV(g_i^i, q_i^i) \) satisfy:

\[
\begin{align*}
(\dot{x}, \dot{y})' (x(t), y(t)) &= 0 \\
(\dot{y}, \dot{u})' (u(t), v(t)) &= 0
\end{align*}
\]  \( t \geq L + \tau_0 \),

(9.12.18)

\( \tau_0 \) being the period of property 9, which corresponds with the value of \( \alpha \) as defined by (9.12.10).

This property may be proved as follows. Since all vectors

\( ((x, y), (u, v)) \in X Y(g_i^i, q_i^i) \times UV(g_i^i, q_i^i) \) satisfy (9.12.17), they
also (property 9) satisfy (9.12.9). This implies (property 12)\ the existence of an 
\((x,y),(u,v)\) \in \tilde{XY}(g^{1},q^{1}) \times \tilde{UV}(g^{1},q^{1})\) satisfying 
(9.12.12) with \(S := \ell^{*}T_{\alpha}\) and thus (property 10) the \validity of property 13.

With the help of the latter property, the proof of the theorem may be completed as follows.

Since 
\(((x(t),y(t)),(u(t),v(t))) \in \tilde{XY}(g^{1},q^{1}) \times \tilde{UV}(g^{1},q^{1})\) 
(9.12.16 and 18.1), all vectors 
\(((x,y),(u,v)) \in \tilde{XY}(g^{1},q^{1}) \times \tilde{UV}(g^{1},q^{1})\) satisfy (property 10) the 
equalities (9.12.17), with \(L = K\). Applying property 13 repeatedly, we find

\[
\begin{align*}
\langle \tilde{\gamma}, \tilde{z} \rangle (x(t),y(t)) &= 0 \\
\langle \tilde{\gamma}, \tilde{x} \rangle (u(t),v(t)) &= 0
\end{align*}
\]

for all vectors \((x,y),(u,v)\) \in \tilde{XY}(g^{1},q^{1}) \times \tilde{UV}(g^{1},q^{1}),
\(i=1,2,...,k\). Since \(\tilde{XY}(g^{1},q^{1}) \times \tilde{UV}(g^{1},q^{1})\),
the inequalities prove the d) part of the theorem.

The e) part of the theorem is implied by d), property 7, and 
by the definition of the sets \(\tilde{XY}(g,q)\) and \(\tilde{UV}(g,q)\).

9.13 \textbf{Theorem.}

An LP-problem (P- or D-directed; exponential; virtually super-
regular) possesses at most one equilibrium combination \((\tilde{x},\tilde{y}), (\tilde{u},\tilde{v})\)
which satisfies simultaneously:

a) \((\tilde{x},\tilde{y}), (\tilde{u},\tilde{v})\) is non-degenerated.

b) Every semi equilibrium path \((x,y),(u,v)\) of \((\tilde{x},\tilde{y}), (\tilde{u},\tilde{v})\)
converges in the following manner:

\[
\begin{align*}
(x(t),y(t)) &= (\tilde{x},\tilde{y}), \ t \to \infty, \\
(u(t),v(t)) &= (\tilde{u},\tilde{v}), \ t \to \infty.
\end{align*}
\]
c) The LP-problem is regular for the initial vector \( x(0) = \hat{x} \).

**Proof.**

Suppose that \((\check{x}, \check{y}), (\hat{u}, \hat{v})\) and \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) are equilibrium combinations, both satisfying a,b, and c. Then, by virtue of theorem 9.12, we may conclude that a period \( S \) exists, such that every optimal solution \((x(t), y(t))\) of the LP-problem with an initial vector \( x(0) = \check{x} \), satisfies:

\[
\begin{align*}
\langle \dot{y}, \check{u} \rangle' \langle x(t), y(t) \rangle &= 0 \\
\langle \dot{y}, \hat{u} \rangle' \langle u(t), v(t) \rangle &= 0
\end{align*}
\]

(9.13.1)

Since \( ((x(t), y(t)), (u(t), v(t))) \) is an optimal solution of the LP-problem with \( x(0) = \check{x} \), it follows from (9.13.1):

\[
\begin{align*}
\langle \dot{y}, \check{u} \rangle' \langle x, y \rangle &= 0 \\
\langle \dot{y}, \hat{u} \rangle' \langle u, v \rangle &= 0
\end{align*}
\]

(9.13.2)

Thus, it appears that \((\check{x}, \check{y}), (\hat{u}, \hat{v})\) and \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) are both equilibrium combinations as well. Then, the definition of non-degenerated equilibrium paths (§9.1) implies that \((\check{x}, \check{y}) = (\hat{x}, \hat{y})\) and \((\hat{u}, \hat{v}) = (\tilde{u}, \tilde{v})\).
10. EQUIVALENT LINEAR PROGRAMMING PROBLEMS OVER A FINITE HORIZON.

10.1 Introduction.

It appears that, if the conditions of theorem 9.12 are satisfied, a period $T$ exists such that all optimal solutions $((x, y), (u, v))$ of such an LP-problem satisfy:

\[
\begin{align*}
\langle \tilde{y}, \tilde{x} \rangle'(x(t), y(t)) &= 0 \\
\langle \tilde{y}, \tilde{x} \rangle'(u(t), v(t)) &= 0 \\
\end{align*}
\]

$\forall t \geq T$. \hspace{1cm} (10.1.1)

So, ever since period $T$ the optimal solutions may be interpreted as semi equilibrium paths belonging to the equilibrium combination $(\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})$ as mentioned in theorem 9.12. Moreover, we found that the optimal solutions $((x, y), (u, v))$ satisfy:

\[
\begin{align*}
\langle \tilde{x}, \tilde{y} \rangle'(x(t), y(t)) &= (\tilde{x}, \tilde{y}), t = m \\
\langle \tilde{u}, \tilde{v} \rangle'(u(t), v(t)) &= (\tilde{u}, \tilde{v}), t = m \\
\end{align*}
\]

$\forall m$. \hspace{1cm} (10.1.2)

Now, let for this equilibrium combination $X^0, Y^0, \tilde{X}^0$ and $\tilde{Y}^0$ be the sets defined by (9.6.17), (9.6.18), (9.6.21), and by (9.6.22). Then (10.1.1) and (10.1.2) imply that all optimal solutions $((x, y), (u, v))$ of this LP-problem satisfy:

\[
\begin{align*}
\langle x(t) \rangle^m_T, \langle y(t) \rangle^m_T \in \tilde{X}^0 \\
\langle u(t) \rangle^m_T, \langle v(t) \rangle^m_T \in \tilde{Y}^0 \\
\end{align*}
\]

$\forall t \geq T$. \hspace{1cm} (10.1.3)

Moreover, one can derive from 9.8-c, d that (10.13) implies:

\[
\begin{align*}
S_p \langle x(t)-\tilde{x} \rangle^m_T \in X^0 \\
\langle \tilde{y}, \tilde{x} \rangle'(u(t)-\tilde{u}, v(t)) \in \tilde{Y}^0 \\
\end{align*}
\]

$\forall t \geq T$. \hspace{1cm} (10.1.4)

$S_p$ and $S_d$ being the matrices defined by 9.3-a,b.
It will appear that this offers the possibility to construct a linear programming problem over a finite horizon, from which all optimal solutions of the original infinite horizon problem can be found. To that end, we shall define a system of linear equalities generated by the sets $X^0$ and $U^0$.

### 10.2 Definitions

For the equilibrium combination $(\bar{X}, \bar{Y}), (\bar{U}, \bar{V})$ as mentioned in theorem 9.12, we define the following matrices:

a) $c^\perp$ and $c^\parallel$, consisting of the real and the imaginary part resp. of the column vectors $q_{ij}$ of matrix $\mathbf{Q}$ (def. 9.5.7), which correspond with eigenvalues $\lambda_{jj}$ of $\mathbf{A}$ (def. 9.6.7) satisfying:

\[
\lambda_{jj} \neq 0 \quad \begin{vmatrix} \frac{\lambda_{jj} - 1}{\lambda_{jj}} \\ \frac{\lambda_{jj} - 1}{\lambda_{jj}} \end{vmatrix} < 2\pi
\]

provided that such eigenvalues exist. (***)

b) $D^\perp$ and $D^\parallel$, consisting of the real and the imaginary part resp. of the column vectors $q_{ij}$ of matrix $\mathbf{Q}$, which correspond with eigenvalues $\lambda_{jj}$ of $\mathbf{A}$ satisfying:

\[
\lambda_{jj} \neq 0 \quad \begin{vmatrix} \frac{\lambda_{jj} - 1}{\lambda_{jj}} \\ \frac{\lambda_{jj} - 1}{\lambda_{jj}} \end{vmatrix} < 1
\]

provided that such eigenvalues exist.

*** In §10.6 we shall revert to this subject.
We observe that these definitions imply that the equalities
\[ \begin{align*}
C^i &= b^i \\
C^j &= b^j
\end{align*} \]  
are valid if and only if, matrix \( H := (Q^T \eta_0)^{-1} \eta \) (def. 9.6.4 and 9.6.7) contains no eigenvalues \( \lambda_{jj} \) satisfying:
\[ \frac{\lambda_{jj} - 1}{\lambda_{jj}} \geq 1. \]
\[ (10.2.1) \]

10.3 Proposition.
For the sets \( X^0 \), \( U^0 \) (def. 9.6.17 and 9.6.19), the \( k \times h_1 \)-matrices \( C^r, C^s \), and the \( k \times h_2 \)-matrices \( B^r, B^s \) defined by 10.2-a,b, the following equalities hold:
\[ \begin{align*}
X^0 &= \{ x^0 : C^r x^0 + C^s z^0 = 0, \ z^0 \in \mathbb{R}^h \} \\
U^0 &= \left\{ u^0 : B^r u^0 + B^s z^0 = 0, \ z^0 \in \mathbb{R}^h \right\}
\end{align*} \]  
\[ (10.3.1) \]

Proof.
The definitions (9.6.13) and (9.6.17) of the sets \( Z \) and \( X^0 \) imply:
\[ \begin{align*}
X^0 &= \{ x^0 \in \mathbb{R}^k : x = Qz, \text{ for some } z \text{ such that } \ \ z_i = 0 \text{ if } \lambda_{ii} = 0 \text{ or } \left| \frac{\lambda_{ii} - 1}{\lambda_{jj}} \right| \leq 1 \}
\end{align*} \]  
\[ (10.3.3) \]
Clearly, (10.3.3) and definition 10.2-a imply (10.3.1).

The definitions (9.6.14) and (9.6.18) of the sets \( W \) and \( U^0 \) imply:
\[ \begin{align*}
U^0 &= \{ u^0 \in \mathbb{R}^k : u^0 = (Q^{-1})^\top v, \text{ for some } v \text{ such that } \ \ v_i = 0 \text{ if } \lambda_{li} = 1 \text{ or } \left| \frac{\lambda_{ii}(\lambda_{ii} - 1)}{\lambda_{ii}} \right| \geq 1 \}
\end{align*} \]  
\[ (10.3.4) \]
Since (10.3.4) can be written:

\[ u^0 = \{ u^0 \in \mathbb{R}^k \mid Q^0 u^0 = v, \text{ for some } w \text{ such that } \\]
\[ w_1 = 0 \text{ if simultaneously } \lambda_i \neq 0, \text{ and } (\lambda_i^{-1})/\lambda_i \leq 1 \}, \]

definition 10.2-b implies:

\[ u^0 = \{ u^0 \in \mathbb{R}^k \mid D^T u^0 = 0, D^T u^0 = 0 \}. \]  \hspace{1cm} (10.3.5)

From (9.6.12) and from definition 10.2-b, one can derive that (10.3.5) may be written:

\[ u^0 = \{ u^0 \in \mathbb{R}^k \mid D^T u^0 = 0, D^T u^0 = 0 \text{ for some } u^0 \in \mathbb{R}^k \}, \]

which is equivalent to (10.3.2).

10.4 Definitions.

Let \((\tilde{x}, \tilde{y}), (\tilde{u}, \tilde{v})\) be an equilibrium combination of an LP-problem as considered in theorem 9.12, and let \(C^T, C^T\) be the matrices defined by 10.2-a, and \(\delta_1, \delta_2, G_1\) the positive numbers of proposition 9.6-i, j. Then, for every period \(T \geq K\), we can associate an LP-problem over a finite horizon to the original infinite horizon problem, in the following manner:

the primal finite horizon problem:

\[ \phi(x, X, Y, Y^2, T) := e^{p^T X} \eta^T p^T X, \]  \hspace{1cm} (10.4.1)

\[ \eta^T (\tilde{u} - \tilde{v}) \tilde{u} + \eta^T \tilde{u} \tilde{v}, \]

to be maximized over the vectors \(\{(x(t), y(t))\}_T, X, Y, Y^2, x_1, x_2, \alpha, \beta, \) which satisfy:
\[ Bx(1) + y(1) = 0(1) \]
\[ Bx(t+1) - Ax(t) + y(t+1) = \gamma_{1}^T x(t+1), \quad t=1, \ldots, T-1 \]
\[ (\mathbf{3} - \mathbf{vA})x - S_{d} Ax(T) + x_{1} - x_{2} = \frac{p_{T-1}}{1-p_{T-1}} s_{d} \]
\[ x(T) + x_{1} = \rho_{T} (x + \delta_{1} s) \]
\[ -x(T) + x_{2} = \rho_{T} (\gamma_{1} s) \]
\[ x + c_{1} x_{1}^{T} - c_{2} x_{2}^{T} = \frac{T-1}{1-p_{T-1}} s_{d}^{T} \]
\[ c_{1}^{T} x_{1} + c_{2}^{T} x_{2} = 0 \]
\[ x(t), y(t) \geq 0, \quad t=1, \ldots, T \]
\[ x_{1}, x_{2}, y_{1}, y_{2} \geq 0 \]

and its dual problem, to be derived by application of the duality rules for linear programming in a finite dimensional space:

\[ \psi(u, v, v_{1}, v_{2}, w_{1}, w_{2}, T) := \langle r_{0}, u, v_{1}, v_{2}, w_{1}, w_{2}, T \rangle - \rho_{T}^{T} (x + \delta_{1} s) y_{1} - \rho_{T}^{T} (\gamma_{1} s) y_{2} \]

\[ = \rho_{T}^{T} (\gamma_{1} s) y_{2} + \frac{T-1}{1-p_{T-1}} s_{d}^{T} w_{1} \]

(10.4.3)

to be minimized over the vectors \((u(t), v(t))_{T}^{T}, u, v_{1}, v_{2}, u_{1}, u_{2}, w_{1}, w_{2}, w_{1}\), which satisfy:
We shall denote the whole consisting of the primal and the dual problem over a finite horizon, by $\overline{\text{LP}}(T)$.

We shall call:

- $\{(x(t),y(t))\}_{t=1}^{T}$ a primal optimal solution of $\overline{\text{LP}}(T)$ if vectors $x, x^1, x^2, y^1, y^2,$ and $z^1$ exist, such that $\{(x(t),y(t))\}_{t=1}^{T}$, $x, x^1, x^2, y^1, y^2,$ and $z^1$ satisfy (10.4.2) and such that, for these vectors, $\phi(x,x^1,x^2;T)$ takes his maximum value.

- $\{(u(t),v(t))\}_{t=1}^{T}$ a dual optimal solution of $\overline{\text{LP}}(T)$ if vectors $u, u^1, u^2, v^1, v^2,$ and $w^1$ exist, such that $\{(u(t),v(t))\}_{t=1}^{T}$, $u, u^1, u^2, v^1, v^2,$ and $w^1$ satisfy (10.4.4) and such that, for these vectors, $\psi(u,u^1,u^2,w^1;T)$ takes his minimal value.

- $\{(x(t),y(t))\}_{t=1}^{T}$ is primal optimal and $\{(u(t),v(t))\}_{t=1}^{T}$ is dual optimal.

Applying the duality properties of linear programming in a finite dimensional space, one can derive that solutions $\{(x(t),y(t))\}_{t=1}^{T}$, $x, x^1, x^2, y^1, y^2,$ and $z^1$ of (10.4.2) and $(10.4.4)$ resp. are optimal if and only if:

\[
\begin{align*}
\mathbb{B}'u(t)-A'u(t+1)-v(t) &= \nu^T\mathbb{P}(t), \quad t=1,\ldots,T-1 \\
\mathbb{B}'u(t)-A'u(t+1)+v(t) &= \nu^T\mathbb{P}
\end{align*}
\]

\[
\begin{align*}
u^T&=\pi^T1 \mathbb{P}_d (\mathbb{U}-\mathbb{E}_d) \\
-u^T&=\pi^T1 \mathbb{P}_d (-\mathbb{U}+\mathbb{E}_d)
\end{align*}
\]

\[
\begin{align*}
(p^T-\pi^T1)\mathbb{U}+v^T &= \pi^T1 \mathbb{P}^p \\
\pi^T1 \mathbb{F}u^1 &= 0 \\
-v^T1 \mathbb{F}u^1 &= 0 \\
0 &\leq u(t), v(t) \leq T, \quad t=1,\ldots,T \\
0 &\leq u^1, v^1, u^2, v^2
\end{align*}
\]
\[
(v(t),u(t))'(x(t),y(t)) = 0, \quad t=1,\ldots,T
\]
\[
u^1,v^1 = 0, \quad u^2,v^2 = 0
\]
\[
x^1,v^1 = 0, \quad x^2,v^2 = 0
\] (10.4.5)

We shall call an associated problem \(\overline{\mathbf{LP}}(T)\) equivalent with respect to the original infinite horizon problem, if simultaneously the following relations between optimal solutions of \(\overline{\mathbf{LP}}(T)\) and the original infinite horizon problem are valid:

a) If \((x,y),(u,v)\) := \((\{x(t)\}_i^T,\{y(t)\}_i^T,\{u(t),v(t)\}_i^T)\) is an optimal solution of the original infinite horizon problem, then \((\{x(t),y(t)\}_i^T,\{u(t),v(t)\}_i^T)\) is an optimal solution of \(\overline{\mathbf{LP}}(T)\).

b) If \((\{x(t),y(t)\}_i^T,\{u(t),v(t)\}_i^T)\) is an optimal solution of \(\overline{\mathbf{LP}}(T)\), then the original infinite horizon problem possesses an optimal solution \((\{x(t),y(t)\}_i^T,\{u(t),v(t)\}_i^T)\) such that:

\[
(x(t),y(t)) = (x(t),y(t))
\]
\[
(t=1,\ldots,T)
\]

\[
(u(t),v(t)) = (u(t),v(t))
\]

10.5 Theorem.

If \((\tilde{x},\tilde{y}),(\tilde{u},\tilde{v})\) is an equilibrium combination of an LP-problem (P- or D-directed; \(x(t) = \tilde{x}, p(t) = \tilde{p}, t \geq 0\); superregular), which possesses the following properties:

a) \((\tilde{x},\tilde{y}),(\tilde{u},\tilde{v})\) is non-degenerated.

b) The matrix \(K\) (def. 9.5.4) possesses no eigenvalues \(\lambda_{ii}\) for which:

\[
\begin{vmatrix}
\lambda_{ii} - \lambda_{ii}
\end{vmatrix} = 0
\]

\(\begin{vmatrix}
\lambda_{ii}
\end{vmatrix} = \gamma_{ii}
\]

c) The associated exponential LP-problem is regular for the initial vector \(x(0) := \tilde{x}\).
then, a period $T^* > T$ exist such that, for every $T > T^*$, the associated problem over a finite horizon $T(T)$ (provided the matrices $C^*$ and $C^T$ exist) is equivalent with respect to the original problem over an infinite horizon.

**Proof.**

Since condition (9.12-b) is implied by 10.5-b, we may, by virtue of theorem 9.12, conclude that:

- A period $T^* > T$ exists such that all optimal solutions $(\{\xi, \eta\}, (\xi, 0))$ of an infinite horizon problem satisfy:

  \[
  \begin{align*}
  (\dot{\xi}, \dot{\eta})^T (\xi(t), \eta(t)) &= 0, \quad t > T^*, \\
  (\dot{\xi}, \dot{\eta})^T (\xi(t), \eta(t)) &= 0.
  \end{align*}
  \]

- All optimal solutions $(\{\xi, \eta\}, (0, 0))$ of the infinite horizon problem converge in the following manner:

  \[
  \begin{align*}
  (\xi(t), \eta(t)) &= (\bar{\xi}, \bar{\eta}), \quad t \to \infty, \\
  (\dot{\xi}(t), \dot{\eta}(t)) &= (\bar{\xi}, \bar{\eta}), \quad t \to \infty.
  \end{align*}
  \]

Moreover, by virtue of theorem 6.21, we may conclude that numbers $N_1$ and $N_2$ exist, such that all optimal solutions $(\{\xi, \eta\}, (0, 0))$ of the infinite horizon problem satisfy:

\[
\begin{align*}
\xi^* / \delta &\in \sigma^0(N_1), \\
0 / \delta &\in \sigma^0(N_2).
\end{align*}
\]

With respect to the positive numbers $\delta_1, \delta_2$ appearing in the associated finite horizon problem, one can derive from (10.5.1) to (10.5.3), and from proposition 9.8-b, that a period $T^* > T$ exists such that all optimal $(\{\xi, \eta\}, (0, 0))$ of the infinite horizon problem satisfy:
Now, consider a finite horizon problem $\mathcal{F}(T)$ with $T \geq T^*$. For every optimal solution $((\mathcal{R}, \mathcal{P}), (\mathcal{G}, \mathcal{Q}))$ of the infinite horizon problem we put:

$$\hat{X} := \frac{1}{p} \sum_{t=1}^{T^*+1} p^{T^*+1-t} \mathcal{G}^t \mathcal{Q}(z), \quad (10.5.5)$$

$$\hat{U} := S_d \mathcal{U}(T^*), \quad (10.5.6)$$

where (10.5.5) exists by virtue of the fact that $\mathcal{G}_n \in L_1$. From (10.5.5) it follows:

$$(x_{T^*+1} - S_d \mathcal{R}(T)) = p^{T^*+1} \sum_{t=0}^{T^*+1} \frac{(P\mathcal{P})^t \mathcal{G}_d}{1 - \rho P \mathcal{P}} \mathcal{Q}_d, \quad (10.5.7)$$

Moreover, since 10.5-b implies that $D^T = C^T$, $b^T = c^T$ (via 10.2.), it follows from (10.5.1), (10.5.2), (10.5.3), (10.5.6), and from proposition 9.3-e, d, that:

$$\begin{align*}
(x_{T^*+1} - S_d \mathcal{G}_d) & \in X^C \\
(\mathcal{G}_d - \mathcal{A}^T)(U - \tau^{T^*+1} S_c \mathcal{G}_d) & \in U^D.
\end{align*}$$

By virtue of proposition 10.3, this implies the existence of vectors $\mathcal{G}^T$, $\mathcal{P}^T$, $\mathcal{Q}^T$, and $\mathcal{Q}_d$ satisfying:

$$\begin{align*}
\mathcal{X} = C^T \mathcal{G}^T - C^T \mathcal{P} & = \frac{p^{T^*+1}}{1 - \rho P \mathcal{P}} \mathcal{Q}_d^T \\
C^T \mathcal{G}^T + C^T \mathcal{Q}_d & = 0
\end{align*} \quad (10.5.8)$$
\[
\begin{align*}
& (\mathbf{y}^1 - \nu^1) \mathbf{u}^* + \phi^* = \pi_{1^*} (\mathbf{y}^1 - \nu^1) \mathbf{u}^* = \pi_{1^*} \mathbf{g}^1 \mathbf{u}^* \\
& \mathbf{c}^\top \mathbf{u}^* + \mathbf{s}^\top \mathbf{u}^* = 0 \\
& \mathbf{c}^\top \mathbf{u}^* + \mathbf{s}^\top \mathbf{u}^* = 0
\end{align*}
\]

From (10.5.4) to (10.5.9), we may conclude that vectors \( \mathbf{y}^1 = 0, \mathbf{y}^2 = 0, \mathbf{u}^1 = 0, \mathbf{u}^2 = 0, \mathbf{g}^1, \mathbf{g}^2, \mathbf{g}^1, \mathbf{g}^2 > 0 \) exist such that

\( ((\mathbf{y}(t), \dot{\mathbf{y}}(t)))^\top \mathbf{x}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{g}^1, \mathbf{g}^2, \mathbf{x}^1, \mathbf{x}^2 \) satisfies (10.4.2) and such that \( ((\mathbf{y}(t), \dot{\mathbf{y}}(t)))^\top \mathbf{y}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{g}^1, \mathbf{g}^2, \mathbf{g}^1, \mathbf{g}^2 \) satisfies

(10.4.4). Moreover, since \( \mathbf{y}^1 = 0, \mathbf{y}^2 = 0, \mathbf{u}^1 = 0, \mathbf{u}^2 = 0 \), it appears that (10.4.5) is satisfied. Thus, we may conclude that

\( ((\mathbf{y}(t), \dot{\mathbf{y}}(t)))^\top \mathbf{y}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{g}^1, \mathbf{g}^2, \mathbf{g}^1, \mathbf{g}^2 \) is an optimal solution of \( \mathbf{L}^\top (\mathbf{T}) \). Hence, condition 10.4-a of the definition of equivalence is satisfied.

To prove that condition 10.4-b is satisfied, we assume that \( ((\mathbf{x}(t), \mathbf{y}(t)))^\top \mathbf{x}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2 \) is a primal optimal solution of \( \mathbf{L}^\top (\mathbf{T}) \), and denote \( \mathbf{x}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2 \) as the vectors such that:

\( ((\mathbf{x}(t), \mathbf{y}(t)))^\top \mathbf{x}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2 \) satisfies (10.4.2).

Since \( ((\mathbf{x}(t), \mathbf{y}(t)))^\top \mathbf{x}, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2 \) is a dual optimal solution of \( \mathbf{L}^\top (\mathbf{T}) \) for which \( \mathbf{g}^1, \mathbf{g}^2 > 0 \), (10.4.5) implies

\[
\begin{align*}
& ((\mathbf{y}(t), \dot{\mathbf{y}}(t)))^\top ((\mathbf{x}(t), \mathbf{y}(t))) = 0, \ t=1, \ldots, T \\
& \mathbf{y}^1 = 0, \mathbf{y}^2 = 0
\end{align*}
\]

So, from (10.4.2) and from proposition 10.3, we may conclude:

\[
\begin{align*}
& ((\mathbf{y} - \mathbf{L}^\top \mathbf{x})^\top \mathbf{g}^1, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2) = \mathbf{x}^0, \\
& ((\mathbf{y} - \mathbf{L}^\top \mathbf{x})^\top \mathbf{g}^2, \mathbf{y}^1, \mathbf{y}^2, \mathbf{x}^1, \mathbf{x}^2, \mathbf{z}^1, \mathbf{z}^2) = \mathbf{x}^0
\end{align*}
\]
\[ \frac{1}{2}^T x(T) - \frac{1}{2} x_0 \leq \delta. \quad (10.5.13) \]

Since:
\[ s_p^2 = (X - \frac{1}{\rho^2} \mathbf{1})^T \mathbf{1} s_p^2, \]
the equality (10.4.11) implies:
\[ (X - \frac{1}{\rho^2} \mathbf{1})^T \mathbf{1} s_p^2 = \Lambda s_p^2 (x(T) - o^T x). \]

With the help of matrix \( \Xi \) defined by (9.6.4), the latter equality can be reduced to:
\[ x - \frac{1}{\rho^2} \mathbf{1} = \frac{1}{\lambda}(X - \frac{1}{\rho^2} \mathbf{1}) s_p^2 (x(T) - o^T x), \]
and with the help of the matrices \( \Lambda \) and \( Q \) defined by (9.5.7) to:
\[ Q^{-1} (X - \frac{1}{\rho^2} \mathbf{1}) s_p^2 (x(T) - o^T x). \quad (10.5.14) \]

From (10.5.14), (10.5.12), and from definition (9.6.17) one can derive:
\[ s_p^2 (x(T) - o^T x) \in \Xi. \quad (10.5.15) \]

By virtue of proposition 9.8-9, the relation (10.5.15) implies the existence of a sequence \((x(t))_{T_t}, (y(t))_{T_t} \in \Xi \times \Xi \) such that \((x(t))_{T_t}, (y(t))_{T_t} \in \Xi \) (def. 9.6.21). Moreover, by virtue of (10.5.13) and proposition 9.8-1, this implies
\[ x(t), y(t) \geq 0, t \geq T_t. \quad (10.5.16) \]

Thus we may conclude that \((x, y) := ((x(t))_{T_t}, (y(t))_{T_t}) \) is a primal feasible solution of the infinite horizon problem. Moreover, from (10.5.1), (10.5.10), and (10.5.6) we may conclude:
\[ \langle 0, x \rangle, \langle 0, y \rangle = 0. \]
and by virtue of \((x(t))_{T+1}^\infty, (y(t))_{T+1}^\infty \) = \(\mathbb{V}^\prime\) (def. 9.6.21):

\[ x_{1/\rho} \in l_\infty, \quad y_{1/\rho} \in l_\infty. \]

Thus by theorem 6.21, it appears that \((x,y)\) is a primal optimal solution of the infinite horizon problem. This proves that, with respect to the primal problem, condition 10.2-b is satisfied.

Now, we assume that \(\{(u(t),v(t))\}_{T}^\infty\) is a dual optimal solution of \(\mathbb{V}(T)\). In a similar manner as the relations (10.5.11) to (10.5.13) are found, we may conclude that a \(U\) exists such that:

\[ b'U(T) - A'S'U = \pi\rho, \]
\[ (A' - \pi A')U - \pi^T \delta_0 U = U' \]
\[ (1/2T^2)U - \delta_0 U |_{t=\infty} < \delta_2. \]

Now, by virtue of proposition 9.8-c, the relation (10.5.18) implies the existence of a \(\{(u(t))_{T+1}^\infty, (v(t))_{T+1}^\infty\} \in \mathbb{V}^\prime\) (def. 9.6.22) such that \(u(T+1) = S^T U\). Moreover, by virtue of (10.5.15) and proposition 9.8-c, we may conclude

\[ u(t), v(t) \geq 0, \quad t \geq T+1. \]

With the help of this result, the proof with respect to the dual optimal solution may be completed in a similar manner as done for the primal optimal solution.

10.5 Remark.

If no eigenvalues \(\lambda_{11}\) exist for which

\[ \left| \frac{\lambda_{11}^{-1}}{\lambda_{11}} \right| < 1, \]
then the matrices $c^f$, $c^d$, $d^f$, and $b^d$ do not exist. In this case the sets $X^0$ and $U^0$ (def. 10.2-3,8) are defined by $X^0 := \{0\}$ and $U^0 := R^N$.

The associated problems over a finite horizon can be written:

$$
\phi(x, X_Y^1, Y^2; T) := \langle p_0^T, x \rangle + \left( T+1 \right) \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)
$$

$$
+ \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)^T (c^d \sigma T+1 \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)

(10.6.1)
$$

To be maximized over the vectors $\{(x(t), y(t))\}^T$, $X$, $Y^1$, $Y^2$, $x^1$, $x^2$ which satisfy

$$
\begin{align*}
B x(1) + y(1) & = \rho^T(1) \\
B x(t+1) - A x(t) + y(t+1) & = \rho^{T+1} (c^d \sigma T+1 \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p) \\
(\Psi - A) x^1 + (d^f \sigma \varepsilon_T^p) x^2 & = \frac{T+1}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)
\end{align*}
$$

$$
x(t) + x^1 = \rho^T (x + x^1) \\
x(t) + x^2 = \rho^T (-x + x^2) \\
x = \frac{T+1}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)

(10.6.2)
$$

and the corresponding dual problem:

$$
u(u, V^1, V^2; T) := \langle p_0^T, u \rangle + \left( T+1 \right) \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)
$$

$$
+ \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)^T (c^d \sigma T+1 \frac{\varepsilon_T^p}{\rho^{T+1}} (d^f \sigma \varepsilon_T^p)

(10.6.3)
$$
to be minimized over the vectors \( ((u(t), v(t)))_1^T, \mathcal{U}, \mathcal{V}_1, \mathcal{V}_2, \mathcal{U}_1, \mathcal{U}_2, \mathcal{V}_2, \) which satisfy:

\[
\begin{align*}
\mathcal{R} u'(t) - \mathcal{A}' u(t+1) - \mathcal{V}(t) &= \pi^T p(t), \quad t = 1, \ldots, T-1, \\
\mathcal{R} u(T) - \mathcal{A}' \mathcal{S}_d u + \mathcal{V}_1 - \mathcal{V}_2 - \mathcal{V}(T) &= \pi^T p
\end{align*}
\]

\[
\begin{align*}
\mathcal{U} - \mathcal{U}_1 &= \pi^T \mathcal{S}_d (\mathcal{U}_2 - \mathcal{U}_1) \\
-\mathcal{U}_1 - \mathcal{U}_2 &= \pi^T \mathcal{S}_d (\mathcal{U}_1 - \mathcal{U}_2) \\
\mathcal{E}' - \mathcal{A}' \mathcal{U} + \mathcal{V} &= \pi^T \mathcal{S}_d \mathcal{E}
\end{align*}
\]

\[
\begin{align*}
u(t), &v(t) \geq 0, \quad t = 1, \ldots, T \\
u_1, &u_2, v_1, v_2 \geq 0
\end{align*}
\]

(10.6.4)

It can be shown that in this case too, theorem 10.5 is valid.

A similar situation may also arise if the non-degenerate equilibrium combination \((\hat{x}, \hat{y}),(\hat{U}, \hat{V})\) is such that \(\hat{x} = 0\) and \(\hat{u} = 0\). Clearly, in that case the only semi equilibrium path possible is:

\[
\begin{align*}
(x(t), y(t)) &= \alpha^T (0, \hat{y}) \\
(u(t), v(t)) &= \pi^T (0, \hat{u})
\end{align*}
\]

\(\alpha \geq 1\).

10.7 Remark.

If the conditions of theorem 10.5 have been satisfied, then it appears that all optimal solutions of the infinite horizon problem can be found with the help of a linear programming problem in a finite dimensional space. Basically, such an infinite horizon problem is hereby solved.

In the solving procedure three phases may be discerned: finding the equilibrium combination, setting up the associated linear
programming problem over a finite horizon according to §10.4 or §10.6 and, finally, solving the finite horizon problem.

Concerning the finding of equilibrium combinations, proposition 8.3 suggests a parametric approach of the linear programming problem defined in §8.2.

When an equilibrium combination has been found satisfying the requirements, then matrices \( C^r \) and \( C^i \) (def. 10.2-a) can be found by calculating the eigenvalues and eigenvectors of matrix \( \mathbf{H} \) (def. 9.9.4).

The best way to solve the associated programming problem over a finite horizon seems to be using a parametric process, in its essence deducible from the proof of theorem 9.12 (viz. def. 9.12.6, def. 9.12.16, and property 13 of this theorem).
REFERENCES.

LIST OF SYMBOLS.

Spaces:

$\mathbb{R}^n$: real $n$-dimensional vector space,

$\mathbb{R}_+^n = \{ x \in \mathbb{R}^n | x_i \geq 0, \ i = 1, 2, \ldots, n \}$.

$1^k$, $1_j^k$, $1_m^k$, $1_n^k$: 24, 25.

$e_0$, $e_k$: 89.

$\mathbb{S}_{x,y,\ldots}^1$, $\mathbb{T}_{x,y,\ldots}^2$: 24, 25, 26.

$x_i \overset{\text{i-m}}{\rightarrow} x_0$: convergence of sequence $(x_i)_i$ to $x_0$.

$x_i \overset{\text{w}}{\rightharpoonup} x_0$: weak convergence, 89.

Sets and vectors:

Int$(C)$: interior of $C$.

$\overline{C}$: closure of $C$.

$\Pi(C)$: power set of $C$.

$S^n_0(M)$: sphere in $\mathbb{R}^n$ with radius $M$, 112.

$X \times Y$: cartesian product of sets $X$ and $Y$.

$X + Y = \{ x + y | x \in X, y \in Y \}$, the sum of sets $X$ and $Y$.

$x^0$: $x$ is positive, i.e.: $x_i > 0, \ i = 1, 2, \ldots$

$x^0$: $x$ is non-negative, i.e.: $x_i \geq 0, \ i = 1, 2, \ldots$

$x^0$: $x 
eq 0$.

$[a,b]$ := $\{ x | a \leq x \leq b \}$ closed interval

$(a,b) := \{ x | a < x < b \}$

$[a,b] := \{ x | a \leq x \leq b \}$

$(x,y)$: the vector with components $(x_1, \ldots, x_n, y_1, \ldots, y_m)$.

$(x(t))_t$ sequence of vectors $x(1), x(2), \ldots$

$(x_i)_i$ sequence of vectors $x^1, x^2, \ldots$.
Mappings, functionals, and matrices.

\( G: X \to Y \): (single-valued) mapping from \( X \) into \( Y \)

\( G: X \to Y(t) \): set-valued mapping from \( X \) into \( Y \)

\( \text{graph} (G;D) \) : 112

\( x'y' \) : inner product of finite dimensional vectors \( x \) and \( y \)

\( \langle x,y \rangle_\omega = \sum_{t=1}^{\Omega} x(t)y(t) \)

\( \langle x,y \rangle_{T,K} = \sum_{t=1}^{\Omega} x(t)'y(t) \)

\( I \) : identity matrix

De ontwikkeling van een theorie van een benaming grotere betekenis aan de bekendheid van de beeldbepaling.

In de literatuur afkomen de benamingen altijd in de beeldbepaling gemakkelijk gebruikt worden. Deze is een eenvoudig algoritme.
Zijn $C_1(Z_1-Z_2)$ en $C_2(Z_1-Z_2)$ twee lineaire transformaties op een eindig dimensionale vectorruimte $Z_1$, met de eigenschap dat voor iedere deelruimte $ZC_1$ geldt:

$$\dim \left( C_1(Z) + C_2(Z) \right) \geq \dim (Z),$$

dan bestaat een vectorruimte $Z \subset Z_1$ en een lineaire transformatie $D: Z \to Z$ zodanig dat een rij $\{z(t)\}_{t\geq 1} \subset Z_1$ dan en slechts dan voldoet aan

$$C_1(z(t+1)) = C_2(z(t)), \quad t \geq 1,$$

als voldaan wordt aan:

$$z(1) = z,$$

$$z(t+1) = D(z(t)), \quad t \geq 1.$$

De resultaten van dit proefschrift geven de indruk dat het bestaan van economische evenwijtspanden sterk afhankelijk is van de hoogte van de diskonterings factor. In het bijzonder lijkt het er op dat een te lage diskonteringsfactor de oorzaak zou kunnen zijn van schoksgewijze economische ontwikkelingen.

Een aantal veronderstellingen welke relevant zijn voor transportverschijnselen van stoffen in leverweefsel, geven aanleiding tot het volgende stelsel differentieel vergelijkingen:

$$\frac{3A}{\partial t} = C_a \left( (1-B) \frac{3A}{\partial x} + A \frac{3B}{\partial x} \right),$$

$$\frac{3B}{\partial t} = C_b \left( (1-A) \frac{3B}{\partial x} + B \frac{3A}{\partial x} \right),$$

waarin $A(t,x)$ en $B(t,x)$ de concentraties voorstellen van twee stoffen op tijdstip $t$ en op plaats $x$.

Een dergelijk stelsel kan van betekenis zijn voor het onderzoek van de leverfuncties met behulp van radioaktieve stoffen.

Een samenwerkingsverband tussen de onderafdeling der Wiskunde van de Technische Hogeschool Eindhoven en de Economische Faculteit van de Katholieke Hogeschool Tilburg, zou gunstig zijn voor onderwijs en onderzoek zowel op het gebied van de toegepaste wiskunde als op het gebied van de economie.

Oopenbaar vervoer gebaseerd op een centraal bestuurd horizontaal liftensysteem moet in staat worden geacht het averigeniveau van taxi's te benaderen, tegen aanzienlijk lagere kosten. Het is daarom wenselijk dat ook in Nederland een onderzoekprogramma voor de bestudering van dergelijke systemen wordt opgesteld.
