ABSTRACT

In this paper we introduce a program package which is a tool for decompositions and analysis of sequential machines. A sequential machine is a mathematical model for discrete, deterministic information processing devices and systems, such as digital computers, digital control units, electronic circuits with synchronized delay elements, as well as other fields like biology, psychology and biochemistry. The package can handle most of functions and topics in research and applications of sequential machines.

ACKNOWLEDGEMENTS

The author is greatly indebted to prof. ir. A. Heetman (*) and prof. ir. M.P.J. Stevens for their support and encouragement to this work. Thanks are also expressed to ir. A. Geurts for his advice with respect to program writing and all members of EB group who gave their help to this work in any way. Dr. L. Jozwiak has made useful discussions and contribution to the new version of DASM for Apollo system and the author would like to record his gratitude here.

Address of the author:

A TOOL FOR DECOMPOSITION AND ANALYSIS
OF SEQUENTIAL MACHINES

0. INTRODUCTION

A sequential machine is a mathematical model for discrete, deterministic information processing devices and systems, such as digital computers, digital control units, electronic circuits with synchronized delay elements, and so on. The term, sequential machine, machine, finite-state machine, finite-state automaton, and automaton are synonyms. Nowadays, sequential machine also plays an important role in designing complex systems by using VLSI devices [3].

In this paper, we introduce a program package - DASM which is a tool for decompositions and analysis of sequential machines. It can deal with most of functions and topics in the research and applications of machines. The emphasizes for discussing each function of DASM are on three aspects: principle, algorithm and example. Therefore, it is a useful tool for teaching, researching and industry applications related to machine theory. Due to the facts that DASM works on the abstract mathematical level and that the theory of machines has a considerable influence, not only on the development of computer systems and their associated languages and software, but also in biology, psychology, biochemistry [19], etc., DASM can naturally be also used in any other area where machine theory serves as a mathematical model.
I. SYSTEM STRUCTURE AND OPERATIONS

1.1 DASM Organization

DASM runs on the following system environment:

- **Hardware**: IBM XT/AT;
- **Operating system**: DOS;
- **Source file language**: Pascal.

With the latest version DASM offers the following functions:

- a) SP partitions;
- b) Partition pairs;
- c) Partition trinity;
- d) Equivalence States;
- e) Minimize a machine;
- f) Decompositions on states;
- g) Parallel full-decompositions.

In addition to those, some functions are also available for file
or data managements:

- h) List directories;
- i) Specify a data file;
- j) Edit a text file.

In the following diagram we list all commands in DASM with
different levels. A notation is used there as

```
A
  | C
  B
```

to denote that DASM goes to menu or function B from menu A under the
command C.
A
assignment of states *

E
equivalence states

D

O
O.C.S.P. partitions

W
Edit a text file
1.2 Menu Driver and Help

DASH runs with different functions by the menu driver. The top menu is like

* DASH(1986): D(ecomp. S(P's P(airs T(rinities -->[HYB V.2.1]

The sign "-->" indicates there are other commands with this level and they can be seen by typing "-->" key. This mechanism is in loop. A submenu can be called by typing a correspondent letter and the menu display is changed to the function. For example, in DASH level, typing "P" we get "Pair function" and the menu shows:

Pair> A(s-s B(s-o C(i-s D(i-o Q uit [HYB V.2.1]
Now, we can calculate the pairs by the four commands.

A help routine is in DASM which can be called in DASM level. Typing "H" DASM displays the help menu and some explanations about DASM. Typing a command in help menu some further explanation is given for some functions.

In DASM there is a program to list a directory. Any subdirectories or files can be listed by this command. It displays each file name in three parts:

```
name.extension filesize
```

where name could be a file name or a subdirectory name and filesize is given in byte. When a directory is larger than one page it just lists a full screen and remains a user to see next parts by typing "space-bar".

A nice pull down menu editor is embedded in DASM. It can be called by typing 'W' in DASM level. With the editor a machine table can be entered or updated very easily. In fact we can use the editor to do any editorial affairs which are related or not related to DASM.
II. Machine Functions

By the definition of machines in [18], generally speaking, we shall present the machine $M = (I, S, 0, \delta, \lambda)$ with an input symbol $x \in I$ while it is in some state, say $s \in S$. The machine then outputs $\lambda(s, x)$ while it moves to state $\delta(s, x)$. This notion is somewhat cumbersome and we shall introduce the idea of mappings (or functions) induced by the input.

From the viewpoint of inputs, the machine functions, $\delta$ and $\lambda$, can be considered as sets of functions induced by all inputs: $\delta = \{\delta_x| \delta_x: S \rightarrow S \text{ and } x \in I\}$ and $\lambda = \{\lambda_x| \lambda_x: S \rightarrow 0 \text{ and } x \in I\}$ where $\delta_x$ and $\lambda_x$ are defined by

$$\forall s \in S \forall x \in I : \delta_x(s) = \delta(s, x) \text{ and } \lambda_x(s) = \lambda(s, x).$$

The $\delta_x$ and $\lambda_x$ are called the next-state function and output function, respectively, with respect to input $x$.

Finally, we make notation as follows:

$$s\delta_x = \delta_x(s) = \delta(s, x) \quad (2.1)$$
$$s\lambda_x = \lambda_x(s) = \lambda(s, x) \quad (2.2)$$

for all $s \in S$ and $x \in I$.

Based on (2.1) and (2.2) we can derive some other functions.

Let $A$ be a set. The power set of $A$ is defined as set $\{a|a \subseteq A\}$ and is denoted by $2^A$ because it has an interesting property: $|2^A| = 2^{|A|}$. Therefore, in other words, $2^A$ is the set of all subsets of $A$. Let $S$ and $0$ be sets of states and outputs of a machine. For power sets $2^S$ and $2^0$, we have the following block functions:

$$\overline{\delta}_x : 2^S \rightarrow 2^S \text{ and } \overline{\lambda}_x : 2^S \rightarrow 2^0$$

are defined by

$$Q\overline{\delta}_x = \{q\delta_x|q \in Q \subseteq S\} \quad (2.3)$$
$$Q\overline{\lambda}_x = \{q\lambda_x|q \in Q \subseteq S\} \quad (2.4)$$

where $x \in I$. 

If \( x \in I \), then \( \delta_x \) and \( \lambda_x \) are defined by

\[
\delta_x = \{ q \in Q \mid q \in Q_1 \wedge x_i \in x \} \quad (2.5)
\]

\[
\lambda_x = \{ q \in Q \mid q \in Q_1 \wedge x_i \in x \} \quad (2.6)
\]

A block function maps a subset of \( S \) into a subset of \( S \) or \( O \).

Let \( A \) be a collection of \( n \)-arrangements of the state set \([26]\), and let \( B \) be a collection of \( n \)-arrangements of the output set, and \( x \in I \).

Then vector functions,

\[
\delta_x : A \rightarrow A \quad \lambda_x : A \rightarrow B
\]

are defined for any arrangement \( a \) in \( A \)

\[
a = (a_1 a_2 \ldots a_n)
\]

\[
a \delta_x = (a_1 \delta_x) (a_2 \delta_x) \ldots (a_n \delta_x) \quad (2.7)
\]

\[
a \lambda_x = (a_1 \lambda_x) (a_2 \lambda_x) \ldots (a_n \lambda_x) \quad (2.8)
\]

It is obvious that \( \delta \) keeps \( n \) endpoints of \( n \) tracks of a machine under input \( x \). When \( n = 1 \) and \( x \in I^* \) it keeps the endpoint under the input sequence.

Let \( x = x_1 x_2 \ldots x_k \in I^* \), \( s \in S \). Then, track functions

\[
\delta_x : S \rightarrow S^* \quad \lambda_x : S \rightarrow O^*
\]

are defined by

\[
s \delta_x = s \delta_{x_1} \ldots x_k
\]

\[
= (s \delta_{x_1}) (s \delta_{x_1 x_2}) \ldots (s \delta_{x_k}) \quad (2.9)
\]

and

\[
s \lambda_x = s \lambda_{x_1} \ldots x_k
\]

\[
= (s \lambda_{x_1}) (s \lambda_{x_1 x_2}) \ldots (s \lambda_{x_1 \ldots x_{k-1}} \lambda_{x_k}) \quad (2.10)
\]

Obviously, \( s \delta_x \) and \( s \lambda_x \) record the tracks of a machine under input sequence \( x \).

From the definition we can derive many interesting properties of the functions. The detailed proofs can be found in [20].
PROPERTIES:

1) \( \forall x, y \in I, \forall s \in S \)
   \[
   s \delta_{xy} = (s \delta_x) \delta_y = s \delta_x \delta_y; \tag{2.11}
   \]
   \[
   s \lambda_{xy} = (s \delta_x) \lambda_y = s \delta_x \lambda_y; \tag{2.12}
   \]

2) \( \forall x = x_1 x_2 \ldots x_k \in I^k, x_i \in I, 1 \leq i \leq k, \)
   \[
   s \delta_x = s \delta_{x_1 x_2 \ldots x_k} = s \delta_{x_1} \delta_{x_2} \ldots \delta_{x_k}; \tag{2.13}
   \]
   \[
   s \lambda_x = s \lambda_{x_1 x_2 \ldots x_k} = (s \delta_{x_1} \ldots \delta_{x_{k-1}}) \lambda_{x_k}; \tag{2.14}
   \]

3) if \( x = \varepsilon \in I^* \), then \( \forall s \in S: s \delta_x = s \) and \( s \lambda_x = \varepsilon \in O^* \) \( \tag{2.15} \)

4) \( \forall Q_1, Q_2 \in S \) and \( \forall x, y \in I: \)
   i) \( Q_1 \subseteq Q_2 \implies Q_1 \delta_x \subseteq Q_2 \delta_x \wedge Q_1 \lambda_x \subseteq Q_2 \lambda_x \) \( \tag{2.16} \)
   ii) \( x_1 \subseteq x_2 \implies Q_1 \delta_{x_1} \subseteq Q_2 \delta_{x_2} \wedge Q_1 \lambda_{x_1} \subseteq Q_2 \lambda_{x_2} \) \( \tag{2.17} \)
   iii) \( x_1 \subseteq x_2 \wedge Q_1 \subseteq Q_2 \)
   \[
   \implies Q_1 \delta_{x_1} \subseteq Q_2 \delta_{x_2} \wedge Q_1 \lambda_{x_1} \subseteq Q_2 \lambda_{x_2} \tag{2.18}
   \]

5) \( \forall Q_1, Q_2 \in S, \forall x \in I: \)
   \[
   Q_1 \delta_x \cup Q_2 \delta_x = (Q_1 \cup Q_2) \delta_x; \tag{2.19}
   \]
   \[
   Q_1 \lambda_x \cup Q_2 \lambda_x = (Q_1 \cup Q_2) \lambda_x; \tag{2.20}
   \]

6) \( \forall Q \subseteq S \forall x, y \in I: \)
   \[
   Q \delta_{x_1} \cup Q \delta_{x_2} = Q \delta_{x_1 \cup x_2}; \tag{2.21}
   \]
   \[
   Q \lambda_{x_1} \cup Q \delta_{x_2} = Q \lambda_{x_1 \cup x_2}; \tag{2.22}
   \]

7) \( \forall Q_1, Q_2 \in S, \forall x \in I, \forall x_1, x_2 \in I: \)
   \[
   (Q_1 \cap Q_2) \delta_x \subseteq Q_1 \delta_x \cap Q_2 \delta_x; \tag{2.23}
   \]
   \[
   Q_1 \delta_{x_1 \cap x_2} \subseteq Q_1 \delta_{x_1} \cap Q_1 \delta_{x_2}; \tag{2.24}
   \]
   \[
   (Q_1 \cap Q_2) \lambda_x \subseteq Q_1 \lambda_x \cap Q_2 \lambda_x; \tag{2.25}
   \]
   \[
   Q_1 \lambda_{x_1 \cap x_2} \subseteq Q_1 \lambda_{x_1} \cap Q_1 \lambda_{x_2}; \tag{2.26}
   \]
8) \( \forall Q_1, Q_2 \in S, \forall x_1, x_2 \in I: \)
\[
(Q_1 \cup Q_2) \hat{\delta}(x_1 \cup x_2) = \bigcup_{i,j=1,2} Q_i \hat{\delta}_{x_j},
\]
\[
(Q_1 \cup Q_2) \hat{\lambda}(x_1 \cup x_2) = \bigcup_{i,j=1,2} Q_i \hat{\lambda}_{x_j}.
\]

9) \( \forall x_1, x_2 \in I, \forall s \in S: \)
\[
s \hat{\delta}_{x_1} x_2 = (s \hat{\delta}_{x_1})(s \hat{\delta}_{x_1} x_2)
\]
\[
s \hat{\lambda}_{x_1} x_2 = (s \hat{\lambda}_{x_1})(s \hat{\lambda}_{x_1} x_2)
\]

10) \( \forall x_1, x_2 \in I^*, \forall s \in S: \)
\[
s \hat{\delta}_{x_1} x_2 = (s \hat{\delta}_{x_1})(s \hat{\delta}_{x_1} x_2)
\]
\[
s \hat{\lambda}_{x_1} x_2 = (s \hat{\lambda}_{x_1})(s \hat{\lambda}_{x_1} x_2)
\]

11) \( \forall x, y \in I \) and \( a \in A: \)
\[
a \hat{\delta}_{x y} = (a \hat{\delta}_{x})(a \hat{\delta}_{y}),
\]
\[
a \hat{\lambda}_{x y} = (a \hat{\lambda}_{x})(a \hat{\lambda}_{y}).
\]

12) \( \forall x = x_1 \ldots x_n \in I^* \) and \( a \in A: \)
\[
a \hat{\delta}_x = (\ldots((a \hat{\delta}_{x_1}) \hat{\delta}_{x_2}) \ldots \hat{\delta}_{x_n})
\]
\[
= a \hat{\delta}_{x_1} \hat{\delta}_{x_2} \ldots \hat{\delta}_{x_n}
\]
\[
a \hat{\lambda}_x = a \hat{\delta}_{x_1} \ldots \hat{\delta}_{x_n-1} \hat{\delta}_{x_n}.
\]

If \( x = \varepsilon \in I^* \), then \( a \hat{\delta}_x = a \) \( a \hat{\lambda}_x = \varepsilon \).
III. DATA STRUCTURE

In DASM, data structure is quite simple. The data we need for DASM is from two aspects: declaration of a machine, and representation of partitions. Here we explain them in details.

3.1 Description of a Machine

Considering two types of machines, Mealy and Moore Machines, we apply arrays for the storages of them because an array exactly corresponds to a machine table.

We take

NumStates, NumInputs and NumOutputs

as global variables to represent the number of states, number of inputs and number of outputs of a machine, respectively. The variables are used throughout all of the programs in the package. That is,

\[
\begin{align*}
\text{NumStates} &= \text{Number of States,} \\
\text{NumInputs} &= \text{Number of Inputs,} \\
\text{NumOutputs} &= \text{Number of Outputs.}
\end{align*}
\]

With above global variables, we have

\[
\text{type Machtable = array[1..NumStates, 0..NumInputs] of integer}
\]

where the two upbounds of the array vary with the size of a machine. In the array, a column just is an input column in the machine table and a row a state row.

The definition of a machine table array is suitable to both Mealy and Moore machines. In case of Mealy machines, we need two arrays, one for transition table and one for output table. And in the case of Moore machine one array is enough both for state transition and outputs where outputs column is the column 0 of machine table array. The

...
entries of the arrays are integers which represent states and outputs. Considering the situation of incompletely specified machines, we use integer 0 to indicate a don't care entry.

**SUMMARY:**

We have made

- **NumStates** = number of states
- **NumInputs** = number of inputs
- **NumOutputs** = number of outputs
- **Input set** = \{1,2,..., NumInputs\}
- **State set** = \{0,1,..., NumStates\}
- **Output set** = \{0,1,..., NumOutputs\}
- **don't care** = 0
- **Moore outputs** = Machtable[-,0]

### 3.2 Enter a Machine Table

A machine table array is the internal form of a machine in DASM. We have to enter a practical machine table into an array. The way DASM applied is to use an DOS Edit program to edit a machine table in text form. The reason for this way is that one can easily enter or update a machine table by a familiar edit routine. DASM will read this text file and transform it into a machine table array. There are some parameters we should tell DASM, such as machine type, Mealy or Moore machine, and the size of a machine. They are put in the first two lines of a machine table text. The first one is 1 or 0. Digital 1 indicates the Mealy machine and 0 the Moore machine. The second line consists of three numbers which represent the numbers of state, input and output in order. The rest of text are the entries: next state, and/or outputs which are in the exactly same form as a machine table. The state rows and input columns are implicitly recognized by DASM.
EXAMPLE:

A machine table:  

<table>
<thead>
<tr>
<th>state</th>
<th>input</th>
<th>1/2</th>
<th>3/3</th>
<th>2/2</th>
<th>4/3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1/1</td>
<td>2/2</td>
<td></td>
<td>3/1</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>4/3</td>
<td>0/0</td>
<td>3/2</td>
<td>1/3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>3/1</td>
<td>3/1</td>
<td>2/2</td>
<td></td>
<td>2/2</td>
</tr>
</tbody>
</table>

data form of the machine:

<table>
<thead>
<tr>
<th>state</th>
<th>input</th>
<th>1</th>
<th>4</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>0</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

* entry = next-state/output  
* entry 0 = don't care

SUMMARY:

Mealy machine data structure:

1

NumStates  NumInputs  NumOutputs  
next-state/output .... next-state/output  
   .  
   .  
next-state/output .... next-state/output

Moore machine data structure:

0

NumStates  NumInputs  NumOutputs  
next-state ... next-state  output  
   .  .  .  
   .  .  .  
   .  .  .  
next-state ... next-state  output
3.3 Representation of Partitions.

A basic data involved in DASM running is a partition. Some other forms of data can be generated by partitions easily. For example, a partition pair consists of two partitions and a trinity of three partitions. Thus, we make a definition of data representation of a partition to cover all data structures in DASM. As we know, a partition is constructed by blocks. So, we can use an array for a partition like

\[
\text{type partition = array \{1..Num\} of block} \quad (3.3)
\]

where \text{Num} could be one of \text{NumStates}, \text{NumInputs} or \text{NumOutputs} depending on the partition type. Furthermore, a block just is a set of elements. In particular, a block is a set of some states, of some inputs or of some outputs. In case of a state partition,

\[
\text{type block = set of state.} \quad (3.4)
\]

and state is an integer type bounded in

\[
\text{type state = 0..NumStates.} \quad (3.5)
\]

DASM uses an array for the storage of partitions to meet the different purposes in the package,

\[
\text{PIarray = array \{0..MaxPartition\} of partition} \quad (3.6)
\]

where \text{MaxPartition} is depended on the memory size of a system. The array can be used not only for partitions, but also for pairs and trinities.

**SUMMARY:**

- \text{state} = 0..\text{NumStates}
- \text{block} = \text{set of state}
- \text{partition} = \text{array \{1..\text{Num}\} of block}
- \text{PIarray} = \text{array \{0..\text{MaxPartition}\} of partition.}
IV. THE SUBSTITUTION PROPERTY PARTITIONS

In this chapter we discuss an important concept that will be used throughout this paper, which is the substitution property (SP) partition.

4.1 Principle

First of all, we should explain what is a partition. Let Q be any set with n finite elements,

\[ Q = \{ q_1, q_2, \ldots, q_n \} \]

Furthermore, let \( \pi \) be a set of some subsets of Q, that is,

\[ \pi = \{ B_1, \ldots, B_k \} \]

Set \( \pi \) is a partition on Q iff

\[ \forall B_i, B_j \in \pi: \quad B_i \cap B_j = \emptyset \quad i \neq j \]

and

\[ \bigcup_{i=1}^{k} B_i = Q \] \hspace{2cm} (4.1)

In other words, a partition is a set of some disjointive subsets which cover all elements of Q. Subset \( B_i \) is called a block of partition \( \pi \) on Q.

Usually, we use \([q]_{\pi}\) to denote the block of \( \pi \) which contains the element \( q \) without explicitly indicating the name of a block. For any two partitions \( \pi, \tau \) on Q, there are two operations defined by,

\[ \pi = \{ B_1, B_2, \ldots, B_k \} \]
\[ \tau = \{ B_1, B_2, \ldots, B_k \} \]
\[ \pi \cdot \Gamma = \{ A \mid \exists B_i, B_j : A = B_i \cap B_j \} \quad (4.2) \]

\[ \pi + \Gamma = \{ A \mid \forall A_0, A_1, \ldots, A_m \in \pi \cup \Gamma \quad A_i \cap A_{i+1} \neq \emptyset \}
A = \bigcup \{ A_0, A_1, \ldots, A_m \} \quad 0 \leq i < m \} \quad (4.3) \]

(4.2) means that the meet of a block in \( \pi \) and a block in \( \Gamma \) forms one block of \( \pi \cdot \Gamma \), if it is not an empty set; (4.3) says that continually joint any two blocks in \( \pi \cup \Gamma \) which have at least one element in common, finally get a block of \( \pi + \Gamma \).

**EXAMPLE:**

Let \( S = \{ 1, 2, 3, 4, 5, 6, 7 \} \),
\( \pi = \{ 1, 3, 2, 5, 4, 6, 7 \} \)
\( \Gamma = \{ 1, 2, 3, 5, 4, 6, 7 \} \)

\[ \pi \cdot \Gamma = \{ 1, 3 \cap 1, 2 = 1, 2, 5 \cap 1, 2 = 2, 1, 3 \cap 3, 5 = 3, \\
2, 5 \cap 3, 5 = 5, 4, 6, 7 \cap 4, 6 = 4, 6, 4, 6, 7 \cap 7 = 7 \} \]
\[ = \{ 1, 2, 3, 4, 6, 5, 7 \} \]

\[ \pi + \Gamma = \{ 1, 2, 3, 5, 4, 6, 7 \} \]

where, \( 1, 2, 3, 5 = \cup \{ 1, 2, 1, 3, 3, 5, 2, 5 \} \)
\( 4, 6, 7 = \cup \{ 4, 6, 4, 6, 7, 7 \} \)

In [20] a calculation way of \( \pi + \Gamma \) by hand was introduced which gave a straightforward method and guarantees the correct result obtained. For the above example, it is illustrated as follows:
For a machine $M = (I, S, O, \delta, \lambda)$, there are three different types of partitions, respectively on input set, state set or output set.

A substitution property (SP) partition is a partition $\Pi$ on $S$ of $M$ such that

$$\forall B \in \Pi \ \forall x \in I \exists B' \in \Pi : \delta_B x \in B'$$

(4.3)

Thus, a partition $\Pi$ has SP iff for each $x$ the next-state function maps all blocks of $\Pi$ into blocks of $\Pi$. On the set of all SP partitions of a machine, partition operations, $+$ and $\cdot$, are closed. That is, the sum (or product) of any two SP partitions is a SP partition. SP partition plays an important role in the algebraic theory of machines. It is the hard-core of most topics on machines which will be shown in the following sections.

4.2 Algorithm

There are several ways to calculate SP partitions of a machine. In DASM we applied the following steps:

step 1. For all pair of $s, t$ in $S$, calculate the smallest SP partitions $\Pi_{s,t}$.

step 2. Do partition additions on set of $\Pi_{s,t}$. Any partition sum of two or more partitions is an SP partition.
4.2.1 The Smallest SP's

To calculate a smallest SP we take several procedures:

Function EXIST is used to reduce the calculations of same pairs of states. For any s, t, if EXIST(s, t) is true, this means that s, t are in the same block of an \( \Pi \), and \( \Pi_{s,t} \) has been already done.

Procedure SMALLSP is a recursive procedure which calculates the smallest SP partitions for a pair of states. Statement

\[ \Pi_1 := \Pi_1 + \Pi_1 \]

order \( \Pi_1 \) to meet the definition of a partition because it is not in partition form during the calls of SMALLSP.

FUNCTION EXIST(S1, S2: integer): boolean;
input: two states, \( s_1 \) and \( s_2 \);
output: if \( s_1 \) and \( s_2 \) are in a block of \( \Pi_1[i] \), EXIST := true;
procedure:
begin
var i: integer;
glovar NumStates: integer;
extvar \Pi_1: partition;
i := 1; EXIST := false;
do i ≤ NumStates →
   if \( s_1 \in \Pi_1[i] \land s_2 \in \Pi_1[i] \) →
      EXIST := true; i := NumStates + 1
   | not(\( s_1 \in \Pi_1[i] \land s_2 \in \Pi_1[i] \)) →
      i := i + 1
fi
od
end
PROCEDURE SMALLSP(S_l, S_2: integer, var PI_l: partition)
input: two states, S_1 and S_2, machine table array;
output: the smallest SP partition PI_l of S_1 and S_2
procedure:
begin var i: integer; glovar NumInputs: integer;
i := 1;
do i ~ NumInputs →
  if not(EXIST(S[S_1,i],S[S_2,i])) →
    PI_l[S[S_1,i]] := PI_l[S[S_1,i]] + [S[S_2,i]];
    SMALLSP(S[S_1,i], S[S_2,i], PI_l); i := i + 1
  | EXIST(S[S_1,i],S[S_2,i]) → i := i + 1
fi
od
PI_l := PI_l + PI_l
end

Algorithm SP
input: machine table array;
output: SP set PI_array;
procedure:
begin var i, j, p = integer; PI_W: partition;
  { smallest sp set }
i := 1; p := 0
do i ~ NumStates-1 →
  j := i + 1;
  do j ~ NumStates →
    SMALLSP(i, j, PI_W);
    if PI_W not exists in PI_array →
      p := p + 1; PI_array[p] := PI_W; j := j + 1
    | PI_W exists in PI_array → j := j + 1
  fi
  od
  { SP set }
  ALLP(1, P, P);
end
In above routins as well as follows, $\delta[]$ means the transition array and $\lambda[]$ the output array of the machine in question. Procedure $\text{ALLP}(1,P,P)$ is a universal procedure to do partition additions on the basic partition set $\text{PArray}[1..P]$ and gives the results in $\text{PArray}$ again by variable $P$ which indicates the last partition position in the array. $\text{ALLP}$ is recursive and terminates when there is no new partition arised by addition of any two partitions in the array.

4.3 Example

Machine table: $a:MO124$.dat shown in Fig. 4.1;
from ir. v. d. Eynden;

Procedure:

step 1. Run DASM by typing DASM under DOS prompt;

step 2. Specify the data file by typing $a:MO124$.DAT;

step 3. Select the function of SP partitions by typing S;

step 4. Specify the output file by typing $a:MO124$.SP;

The result is in file $a:MO124$.sp and shown in Fig. 4.2.

Fig. 4.1 Machine $a:MO124$.dat

SP PARTITION OF $a:MO124$.dat

---

Fig. 4.2 The SP partitions of $a:MO124$.dat
In the result file a partition is represented in a little different way. The elements in the same block are bounded by a pair of parentheses and separated by commas. Blocks in a partition are bounded by a pair of braces and separated by semicolons. For example, partition

\[(1,2,3,4,5,6,7)\]

is written as

\[\{(1,2);(3,4);(5,6,7)\}\]

in the result file.
V. PARTITION PAIRS

5.1 Principle

A partition pair is a pair of partitions with some restrictions. Due to the three sets, input, state and output, there are four different types of pairs in machine theory.

An S-S pair consists of two state partitions. One is related to present states and another to nest-states. The two state partitions satisfy the following condition:

Let $\Pi, \Gamma$ be two partition on set $S$ of $M$.

$$\Pi = \{A_1, A_2, \ldots, A_m\}$$
$$\Gamma = \{B_1, B_2, \ldots, B_n\}$$

$(\Pi, \Gamma)$ is an S-S pair $\iff \forall a \in \Pi \ \forall x \in I \ \exists b \in \Gamma: A \delta_x \in B$ (5.1)

Thus, if every block of $\Pi$ can be mapped into a block of $\Gamma$ by every input of the machine, $\Pi$ and $\Gamma$ form an S-S pair. That $(\Pi, \Gamma)$ is an S-S pair indicates that for the states in the same block of $\Pi$, their next-states still in the same block of $\Gamma$. An S-S pair gives the information dependence between present states and next states of a machine.

By the same way we can have the definitions of other three pairs. Let $\Pi$ be a partition on state set $S$, and $\Gamma$ on input set $I$, $\Omega$ on output set $O$.

Then,

$(\Pi, \Omega)$ is an S-O pair

$\iff \forall a \in \Pi \ \forall x \in I \ \exists c \in \Omega: A \delta_x \in C$ (5.2)

$(\Gamma, \Pi)$ is an I-S pair

$\iff \forall b \in \Gamma \ \forall s \in S \ \exists a \in \Pi: s \delta_b \in A$ (5.3)

$(\Gamma, \Omega)$ is an I-O pair

$\iff \forall b \in \Gamma \ \forall s \in S \ \exists c \in \Omega: s \delta_b \in C$ (5.4)
Again, the three pairs depict the information flow dependences between two of inputs, states and outputs. Pairs are important concepts in state assignment, simplification etc. which will be discussed later. There are two operations on the set of some pairs. One is pair addition and another pair multiplication with following definitions.

Let \((\pi_1, \tau_1)\) and \((\pi_2, \tau_2)\) be pairs with same attribution

\[
(\pi_1, \tau_1) + (\pi_2, \tau_2) = (\pi_1 + \pi_2, \tau_1 + \tau_2) \quad (5,5)
\]
\[
(\pi_1, \tau_1) \cdot (\pi_2, \tau_2) = (\pi_1 \cdot \pi_2, \tau_1 \cdot \tau_2) \quad (5,6)
\]

The operations are closed on the set of pairs. That is, the pair sum and pair product of any two pairs are pairs. We should mention it that the conclusion is hold only for the pairs with same attribution. For example, the pair sum or product of two S-S pairs is an S-S, and so on.

For the two components of a pair we have special names for them. The first one is M-partition and the second m-partition. Let \((\pi, \tau)\) be a pair. Then, \(\pi\) is partition of \(\tau\) and \(\tau\) is m-partition of \(\pi\). Pair \((\pi, \tau)\) can be called an Mm pair.

5.2 Algorithm

In DASM, a pair set was found by the algorithm below.

Algorithm PAIR (PairType: CHAR);
input: PairType = A for S-S pair
= B for S-O pair
= C for I-S pair
= D for I-O pair;
Machine table arrays;
output: pair set of PairType
procedure:
begin var i: integer; glovar CurrentPI: integer;
  BmPIS2(PairType, 1, CurrentPI);
  ALLP2(PairType, 1, CurrentPI, CurrentPI);
do i ≤ CurrentPI →
MPI(PairType, PIarray[i], PIW);
writepair( PIW, PIarray[i]);
i := i+1

end

In the algorithm, procedure BmPIS2 calculates all basic m-partitions; ALLP2 does partition additions on the m-partitions to get more m-partitions, and MPI gives a M-partition for one m-partition in the set. Writepair writes the pair on a file, a disk or a printer.

5.3 Example

Machine table: a:me69fo.dat;
shown in Fig. 5.1

Procedure:
step 1. Run DASM by typing DASM
   under DOS prompt;
step 2. Select the function of
   partition pairs by
typing P;
step 3. Specify the data file
   by typing a:me69fo.dat;
step 4. Select the function of
   pairs by typing A,B,C,D;
step 5. Specify the output file
   by typing a:me69fo.pp;

Fig.5.1 Machine me69fo.dat

The result is in file a:me69fo.pp and shown in Figs. 5.2-5.5.
Fig. 5.2 S-S pairs

Fig. 5.3 I-S pairs

Fig. 5.4 S-O pairs

Fig. 5.5 I-O pairs
VI. PARTITION TRINITIES

6.1 Principle

A partition trinity (PT) is a triple of three partitions on input set, state set and output set respectively. The three partitions are restricted by some conditions defined as follows.

Let \( \mathcal{A} \) be a partition on \( S \), \( \mathcal{T} \) on input set \( I \) and \( \mathcal{N} \) on output set \( O \) of a machine \( M \). Then,

\[
(T, \mathcal{A}, \mathcal{N}) \text{ is a partition trinity } \iff \forall A \in \mathcal{A} \forall B \in \mathcal{T} \exists A' \in \mathcal{A} \exists C \in \mathcal{N}:
\]

\[
A \delta B \subseteq A' \wedge A\lambda B \subseteq C. \quad (6.1)
\]

(6.1) is a general definition on any machines, completely or incompletely specified machines. For a completely specified machine, we can prove that (6.2) is equivalence to (6.1).

\[
(T, \mathcal{A}, \mathcal{N}) \text{ is an PT } \iff (T, \mathcal{A}) \text{ is an I-S pair } \\
\wedge (T, \mathcal{N}) \text{ is an I-O pair } \\
\wedge (\mathcal{A}, \mathcal{N}) \text{ is an S-S pair } \\
\wedge (\mathcal{A}, \mathcal{N}) \text{ is an S-O pair } \quad (6.2)
\]

Therefore, (6.2) also provides another way to determine an PT based on the calculations of pairs. The proof of (6.2) is omitted and can be found the details in [20]

On the set of partition trinities there exist two operations, partition addition \( \oplus \) and partition multiplication \( \odot \). Let \( (T_1, \mathcal{A}_1, \mathcal{N}_1) \) and \( (T_2, \mathcal{A}_2, \mathcal{N}_2) \) be any two PT's on a machine \( M \). Then,

\[
(T_1, \mathcal{A}_1, \mathcal{N}_1) \oplus (T_2, \mathcal{A}_2, \mathcal{N}_2) \\
= (T_1 + T_2, \mathcal{A}_1 + \mathcal{A}_2, \mathcal{N}_1 + \mathcal{N}_2)
\]

\[
(T_1, \mathcal{A}_1, \mathcal{N}_1) \odot (T_2, \mathcal{A}_2, \mathcal{N}_2) \\
= (T_1 \ast T_2, \mathcal{A}_1 \ast \mathcal{A}_2, \mathcal{N}_1 \ast \mathcal{N}_2) \quad (6.3)
\]
It was proved that two operations are closed on the set of all PT's of M [20]. And there are some interesting properties on the set of all PT's. Let T be the set of all PT's of M. Then,

\[ <T; \emptyset, \emptyset, T_1, T_0> \]

is an algebraic system called trinity algebra. The two elements, \( T_1 \) and \( T_0 \), are identity and zero trinities defined by

\[ T_1 = (I(I), \pi(I), \Lambda(I)) \]

and \[ T_0 = (I(O), \pi(O), \Lambda(O)) \]

(respectively). It says if the three partitions of an PT are identity (or zero) partitions, the PT is an identity (or zero) trinity. An PT gives the information flow dependence between inputs, states and outputs simultaneously. The concept of partition trinities is core of full-decompositions to be discussed later.

6.2 Algorithm

The calculation for PT's can be done by (6.1) or (6.2). We noted that in (6.2) an \( S-S \) pair \( (\pi, \pi) \) means that \( \pi \) has SP. Then, that calculate SP partition first and further get other partitions is an easy way for the purpose. A complete description of this way is in the following algorithm.

Algorithm PT:

*input*: machine table arrays;

*output*: PT set;

*procedure*:

begin

var i: integer;

get all \( N \) SP partitions;

do i := N ->

\[
\text{MPI}(3, \text{PIarray}[i], \text{PISO1});
\]

\[
\text{MPI}(2, \text{PIarray}[i], \text{PIi});
\]

\[
\text{RMPI}(4, \text{PIi}, \text{PIO}_2);
\]

if $\Pi_01 = \Pi_02 \rightarrow$

\[(\Pi_i, \Pi\text{array}[i], \Pi_01) \text{ is an PT;}
\]
\[i := i+1\]
\[\text{if } \Pi_01 \neq \Pi_02 \rightarrow i := i+1\]

end

In above algorithm,

get all $N$ SP partitions;

is a procedure discussed before, which produce all SP partitions kept in $\Pi\text{array}[1..N]$. After getting the SP partitions, we search them one by one with the following step:

$\text{RMPI}(3, \Pi\text{array}[i], \Pi_01)$;

finds the $m$-partition of $\Pi\text{array}[i]$. First parameter instructs the procedure to work on the I-S pair.

$\text{RMPI}(4, \Pi_i, \Pi_02)$;

produce the $m$-partition for $\Pi_i$ and first parameter means this is an I-O pair. Finally, we have to test whether $\Pi_01$ and $\Pi_02$ are the same partition. If they are identical it means $(\Pi_i, \Pi\text{array}[i], \Pi_01)$ is an PT. Otherwise not.

An alternative way for last procedure call to find the $m$-partition $\Pi_02$ of $\Pi_i$ is to judge if $(\Pi_i, \Pi_01)$ is an I-S pair which can be easily implemented by making a new procedure.

In the algorithm, in order to simplify the description, we ignore parameters which are used to speed up the calculation and can be easily understood from source programs.
6.3 Example

Machine table: a:me8886.dat shown in Fig. 6.1.

Procedure:
step 1. Run DASM by typing DASM under DOS prompt;
step 2. Select the function of trinity by typing T;
step 3. Specify the data file by typing a:me8886.dat;
step 4. Select the function of basic PT's by typing B;
step 5. Specify the output file by typing a:me8886.bpt.

The result is in file a:me8886.bpt and shown in Fig. 6.2.

Fig. 6.1 Machine a:me8886.dat

Fig. 6.2 PT's of a:me8886.dat
VII. EQUIVALENT STATES

7.1 Principle

Equivalent states are states that for any input sequence applied to the machine, the output sequences are identical. Therefore, equivalent states are undistinguishable states in the behaviour of machines.

Symbolically, we have

\[
S \simeq T \iff \forall x \in I^*: s \lambda_x = t \lambda_x \tag{7.1}
\]

The determination of two states, of course, can be carried out by (7.1). But, to search for all input sequence is time-consuming and, sometimes, probably impossible. We should try other way for this. We noted that there is the concept of output consistent SP (O.C.S.P) partitions defined as follows.

Let \( \Pi \) be an SP partition. If for all \( x \) in \( I \) and all pair of \( s \) and \( t \) in \( S \),

\[
[s] = [t] \implies s \lambda_x = t \lambda_x \tag{7.2}
\]

then \( \Pi \) is an O.C.S.P. In other words, an O.C.S.P partition is an SP partition in which all elements in the same block have identical outputs.

In (7.1), from the definition of \( \lambda \), we know, for any input sequence \( X = x_1x_2...x_n \) and \( s, t \in S \)

\[
s \lambda_x = s \lambda_{x_1x_2...x_n} = (s \lambda_{x_1})(s \lambda_{x_1}^2)x_2...(s \lambda_{x_1}^n)\lambda_{x_n}
\]

\[
t \lambda_x = (t \lambda_{x_1})(t \lambda_{x_1}^2)x_2...(t \lambda_{x_1}^n)\lambda_{x_n} \tag{7.3}
\]

Since \( \Pi \) has SP, for any input sequence \( X \) in \( I^* \)

\[
[s \delta_X]_\Pi = [t \delta_X]_\Pi \tag{7.4}
\]

and from (7.2),
Repeatedly applying (7.4) and (7.5) to (7.3) we obtain

\[ s^{\lambda_x} = t^{\lambda_x} \]

which means that \( s \) and \( t \) are equivalent states from (7.1). Conclusively, we have proved that

If \( \Pi \) is an O.C.S.P, then the blocks of \( \Pi \) are sets of states which are equivalent to each other. (7.6)

The conclusion shows a way to us for finding equivalent states: find an S.P partition and check if it is output consistent. If it is then the partition gives the equivalent state classes.

### 7.2 Algorithm.

An algorithm based on (7.6) is shown as follows.

**Algorithm EQStates;**

**input:** machine table arrays;

**output:** O.C.S.P partition set and equivalent state classes;

**procedure:**

begin

var \( i, j \) : integer;

get all \( N \) SP partitions;

(check O.C. property)

\( i := 1; j := 0; \)

\[ \text{do } i \leq N \rightarrow \]

if \( \text{PIarray}[i] \) has O.C.S.P \( \rightarrow \)

\( j := j + 1; \text{PIarray}[j] := \text{PIarray}[i]. \)

\( \text{fi} \)

i := i + 1

od

if \( j \geq 1 \) \( \rightarrow \) PIarray[1] gives equivalent state classes.

\( \text{fi} \)

end
In the above algorithm, "get all N SP partitions" is realized by the early procedure of SP partitions. The partitions are put in PIarray in the order of increasing block numbers of partitions. This lets us get the largest class of equivalent states.

The step "PIarray[i] has O.C.S.P" is done by a small procedure by which the outputs of states in every block for all inputs are checked to see if they are identical. Once failure for some block, the procedure stops and returns false of O.C.S.P for the SP partition.

7.3 Example

Machine table: a:me1242.dat shown in Fig. 7.1.

Procedure:

* step 1. Run DASM by typing DASM under DOS prompt;
* step 2. Specify the data file by typing a:me1242.dat;
* step 3. Select the function of O.C.S.P by typing O;
* step 4. Specify the output file by typing a:me1242.osp.
* step 5. Select the function of equivalent states by typing E;
* step 6. Specify the output file by typing a:me1242.eqs.

The result is in file a:me1242.osp and a:me1242.eqs shown in Figs. 7.2 and 7.3.

This example was from [21].
Fig. 7.2 O.C.S.P partitions of a:me1242.dat

---

Fig. 7.3 The equivalent state classes of a:me1242.dat
VIII. MINIMIZING MACHINES

8.1 Principle

For a completely specified machine, to minimize it is easily done by an O.C.S.P partition. Firstly, find the maximal equivalent state classes. Secondly, take each equivalent state class as a new state for the reduced machine. Finally, the output of a new state comes from one state in the correspondent block.

Let $\pi = \{A_1, A_2, \ldots A_m\}$ be the maximal O.C.S.P partition of machine $M$ and $M'$ be the reduced machine of $M$. So,

$$M = (I, S, O, \delta, \lambda)$$
and $$M' = (I', S', O', \delta', \lambda')$$
where $I' = I$; $O' = O$; $S' = \pi$;

$$\forall A \in \pi \forall x \in I \exists s \in A : A\delta'_x = [A\delta_x]_\pi$$
and $$A\lambda'_x = s\lambda_x.$$

(8.1)

(8.2)

8.2 Algorithm

Algorithm MinMach;

input: machine table arrays;
output: minimized machine $M$;
procedure:
begin
var $i, j, \text{nextstate}, \text{output}$: integer; $\text{PIW}$: partition;
get a maximal O.C.S.P partition $\text{PIW}$;
write inputs;
i := 1;
do $i \leq |\text{PIW}|$ +
  get a new line;
j := 1;
do $j \leq \text{NumInputs}$ +
  write(i);
  FindaState($\text{PIW}[i], s$);
FindaBlock(\(s[j], PIW, B\));
nextstate := B;
output := \(\lambda [s,j]\);
\[\text{write}(\text{nextstate}, ",/", \text{output});\]

end

The procedure "get a maximal O.C.S.P partition" is basically like the algorithm EQStates; "write inputs" makes the headers of all inputs; FindaState takes a state \(s\) from PIW[i]; FindaBlock puts the block \(B\) in PIW, which contains state \(s\); the reduced machine is put on a printer or on a disk file.

8.3 Example

Machine table: a:mel222.dat shown in Fig. 8.1.

Procedure:

\begin{itemize}
  \item \textbf{step 1.} Run DASM by typing \texttt{DASM} under DOS prompt;
  \item \textbf{step 2.} Select the function of minilizing machines by typing H;
  \item \textbf{step 3.} Specify the data file by typing \texttt{a:mel222.DAT};
  \item \textbf{step 4.} Specify the output file by typing \texttt{a:mel222.min}
\end{itemize}

\begin{verbatim}

IX. DECOMPOSITIONS ON STATES

9.1 Principle

Decompositions of a machine were proposed in 1960's. During that time to reduce the internal components was mainly reason due to the techniques of integrated circuits. A reduction of internal component largely depends on the reduction of states of a machine. Decomposition theory was such a theory by which we could make two or more machines each of them has fewer states and works together to realize the behaviour of the original machine.

Decompositions on states can be classified in two types. One is parallel decomposition. That is, the two component machines work independently with common inputs and outputs. Another is serial decomposition. On the connection of two component machines, one of them takes inputs from another one's states or outputs. Thus, the second machine (we call it a tail machine) works not only on the common inputs but also on the results of the first machine.

Decomposition theory shows that for a parallel decomposition, we must find two orthogonal SP partitions. The SP partitions can be used for forming the component machines of the parallel decomposition. If there do not exist such two SP partitions, the machine is said not to be parallelly decomposable. Similarly, for a serial decomposition we need an SP partition and a partition that they are orthogonal.

SUMMARY:

Let \( M \) be a machine, \( M_1 \) and \( M_2 \) be two component machines.

\[
M \sim M_1 \parallel M_2 \iff \exists \pi, \Gamma \text{ on } M:
\]

\[
(\pi \text{ and } \Gamma \text{ have SP}) \land \pi \cdot \Gamma = \pi(0) \quad (9.1)
\]

where \( M_1 = (I, \pi, \delta') \); \( M_2 = (I, \Gamma, \delta'') \);

\[
\forall A \in \Pi \forall x \in I: \ A\delta_x' = [A\delta_x]_{\pi} \quad (9.2)
\]

\[
\forall B \in \Gamma \forall x \in I: \ B\delta_x'' = [B\delta_x]_{\pi} \quad (9.3)
\]

\[
M \sim M_1 \rightarrow M_2 \iff \exists \pi, \Gamma \text{ on } M:
\]
(\pi \text{ has SP}) \land (\pi \cdot \Gamma = \pi(0)) \quad (9.4)

\text{where } M_1 = (I, \pi, \delta'); \quad M_2 = (\pi \times I, \Gamma, \delta'') \quad (9.5)

\forall A \in \pi \quad \forall x \in I: \quad A\delta'_x = [A\delta_x]_\pi \quad (9.6)

\forall B \in \Gamma \quad \forall x \in I \quad \forall A \in \pi:

B\delta''_{(A,x)} = [(A \cap B)\delta_x]_\pi \quad (9.7)

\text{and } \forall s_1 \in \pi, s_2 \in \Gamma: \lambda'(s_1, s_2, x) = (s_1 \cap s_2)\lambda_x \quad (9.8)

\text{where } \lambda' \text{ is the mapping for the output of connections.}

9.2 Algorithms

The algorithms for decompositions on states largely rely on SP partitions. Once getting some SP partitions, we need find two SP partitions their product is zero-partition. In the case of serial decomposition we should calculate a partition from one SP partitions. We take the largest one to get an optimum decomposition, that is, the component machines have the fewest states.

Algorithm PDECOM;
input: machine table;
output: two component machines \( M_1 \) and \( M_2 \);
procedure:
begin var, i, j, i1, j1: integer; find: boolean;
get all N SP partitions;
if N=0 \then no paralled decomposition; exit
\| N\neq0 \then
    find := false; i := 0;
    do (not find) or i \leq N \then
        i := i+1; j := i+2;
        do (not find) or j \leq N \then
            if PIArray[i] \cdot PIArray[j] = \pi(0) \then
                find := true;
            \| PIArray[i] \cdot PIArray[j] \neq \pi(0) \then
                j := j+1;
        fi
    od
fi
if not find \( \leftrightarrow \) not parallel decomposable; exit

\( \text{find} \leftrightarrow \text{(build the component machines)} \)

\( i1 := 1; \)

\( \text{do } i1 \leq |\text{PIarray}[i]| \rightarrow \)

\( j1 := 1; \)

\( \text{do } j1 \leq \text{NumInputs} \rightarrow \)

\( \text{findastate(PIarray}[i,i1], s); \)

\( \text{findablock(PIarray}[i], \delta[s,j], B); \)

\( M_{ij}[i1,j1] := B; \)

\( j1 := j1 + 1 \)

\( \text{od}; \)

\( i1 = i1 + 1 \)

\( \text{od} \)

\( i1 := 1 \)

\( \text{do } i1 \leq |\text{PIarray}[j]| \rightarrow \)

\( j1 := 1; \)

\( \text{do } j1 \leq \text{NumInputs} \rightarrow \)

\( \text{findastate(PIarray}[j1,i1], s); \)

\( \text{findablock(PIarray}[i], \delta[s,j], B); \)

\( M_{ij}[i1,j1] := B; \)

\( j1 := j1 + 1 \)

\( \text{od}; \)

\( i1 = i1 + 1 \)

\( \text{od} \)

fi

end

Algorithm SDECOMP;
input: machine table arrays;
output: component machines \( M_1 \) and \( M_2 \) of a serial decomposition;
procedure:
begin var i1, j1, j2 : integer;
get all \( N \) \( S \) \( P \) partition;
if \( N = 0 \rightarrow \) no serial decomposition; exit
\( \mid N \neq 0 \rightarrow i1 := 1; \)
do  il ≤ |PIarray[1]| →
    j1:=1;
    do  j1≤NumInputs →
        findastate(PIarray[1,il],s);
        findablock(PIarray[1], δ[s,j1], B);
        M_1[il,j1]:=B;
        j1:=j1+1
    od;
    il:=il+1
od

ORTHPART(PIarray[1], PIW);

i1 := 1;
do  il ≤ |PIW| →
    j1:=1; j2:=1
    do  j1≤|PIarray[1]| →
        do  j2≤NumInputs →
            s1 := PIW[i1]·PIarray[1,il];
            findablock(PIW, δ[s1,j2], B);
            M_2[il,(j1,j2)]:=B;
            j2:=j2+1
        od;
        j1:=j1+1
    od
    il:=il+1
od
fi

The procedure ORTHPART calculates a partition PIW which is orthogonal to PIarray[1]. FindaState and FindaBlock are the same as used before. M_1 and M_2 are two machine table arrays that keep the entries for component machines in the decompositions.
9.3 Example

Machine tables: a:me622.dat shown in Fig. 9.1 from [21]; a:me722.dat shown in Fig. 9.2 from [3];

Procedure:
step 1. Run DASM by typing DASM under DOS prompt;
step 2. Select the function of decompositions on states by typing D;
step 3. Specify the data file by typing a:me622.DAT;
step 4. Select the function of parallel decomposition by typing P;
step 5. Specify the output file by typing a:me622.pde;
step 6. Specify the data file by typing a:me722.DAT;
step 7. Select the function of serial decomposition by typing S;
step 8. Specify the output file by typing a:me722.sde.

The result is in file a:me622.pde and a:me722.sde and shown in Figs. 9.3 and 9.4

10.1 Principle

In last chapter we have known how a machine can be decomposed on its states. That is, the component machines have few states. Usually, the component machines keep the same sizes of input set and output set as the original machine. The decomposition results in a partition only on the internal elements of a circuit. In this chapter, we deal with the decomposition both on state set and on input and output sets. This is so-called full-decomposition of sequential machines. An important characteristic of a full-decomposition is that we can make decomposition on the pins and connections of systems.

A full-decomposition is defined as follows.

Let $M=(I, S, 0, \delta, \lambda)$ be a Mealy machine. From the study in [20], it is proved that if there are two partition trinities which are orthogonal, then $M$ can be realized by the parallel connection of two smaller machines which are formed by the two partition trinities. That is,

$$T_1 \circ T_2 = T(0)$$

$$\Rightarrow M = M_1 \parallel M_2$$

(10.1)

where $T_1$ and $T_2$ are two orthogonal PT's and

$$T_1 = (T_1, \pi_1, \Omega_1)$$

and

$$T_2 = (T_2, \pi_2, \Omega_2)$$

$$M_1 = (T_1, \pi_1, \Omega_1, \delta', \lambda')$$

$$M_2 = (T_2, \pi_2, \Omega_2, \delta'', \lambda'')$$

The transition functions and output functions are defined by

$$\forall A_1 \in \pi_1 \quad \forall B_1 \in \Gamma_1:$$

$$A_1 \delta_{B_1} = [A_1 \overline{\delta}_{B_1}]_{\pi_1}$$

(10.2)

$$A_1 \lambda_{B_1} = [A_1 \overline{\lambda}_{B_1}]_{\Omega_1}$$

(10.3)
and \[ \forall A_2 \in \Pi_2 \ \forall B_2 \in \Gamma_2 : \]
\[ A_2 \delta_{B_2} = [A_2 \delta_{B_2}]_{\Pi_2} \]
\[ A_2 \lambda_{B_2} = [A_2 \lambda_{B_2}]_{\Omega_2} \] (10.4) (10.5)

The partition trinities keep that for any A1 and B1, A1 \(\delta_{B_1}\) is certainly contained in and only in a block of \(\Pi_1\), and that A1 \(\lambda_{B_1}\) is certainly contained in and only in a block of \(\Omega_1\). It is the same for (10.4) and (10.5). Also, the orthogonal property of two PT's guarantees each element in original machine sets of state, input and output is mapped into one element in \(M_1\) and one element in \(M_2\), e.g.

\[ \forall s \in S: \ s \rightarrow ([s]_{\Pi_1},[s]_{\Pi_2}) \] (10.6)
\[ \forall x \in I: \ x \rightarrow ([x]_{\tau_1},[x]_{\tau_2}) \] (10.7)
\[ \forall y \in O: \ y \rightarrow ([y]_{\Lambda_1},[y]_{\Lambda_2}) \] (10.8)

10.2 Algorithm

Using the algorithm for PT's in chapter 6 we can find the orthogonal PT's. If there exist no such PT's, the given machine is not full-decomposable. For the orthogonal PT's, using (10.2) through (10.5), the component machines \(M_1\) and \(M_2\) can be formed. The mapping can be easily obtained based on (10.6), (10.7) and (10.8).

Algorithm PFdecomp;
input: machine table arrays;
output: two component machine tables;
procedure:
begin
var N: integer; MS1,MO1,MS2,MO2: MachType;
get all N PT's;
if N<6 \Rightarrow "it is not full-decomposable", exit;
end sub

do there are two largest orthogonal trinities:

PT1 and PT2 \rightarrow

\( \text{SETSUBM}(PT_1, MS_1, MO_1) \);
\( \text{SETSUBM}(PT_2, MS_2, MO_2) \);
set mappings;
In the algorithm, we judge $N>6$ because an PT is located in three partitions. If $N<6$, it means there are no two PT's which implies there is no parallel full-decomposition. The do loop finds all pairs of orthogonal partition trinities and set up the corresponding component machines based on the PT's. SETSUBM is a procedure which calculates the transition and output table. The results of SETSUBM are two machine table arrays. "Write machine tables" writes the component machine table arrays on a file or on a printer.

10.3 Example

Machine table: a:me8886.dat shown in Fig. 6.1;

Procedure:

step 1. Run DASM by typing DASM under DOS prompt;
step 2. Select the function of full-decompositions by typing F;
step 3. Specify the data file by typing a:me8886.dat;
step 4. Select the function of parallel full-decomposition by typing P;
step 5. Specify the output file by typing a:me8886.pfd.

The result is in file a:me8886.pfd and shown in Figs. 10.1-10.9.

Fig. 10.9 Full-decomposition 9
XI. ISSM.

In practical design, there are some machines which contain don't care entries. In this case, we have to make some modifications on above algorithms to calculate some functions on incompletely specified sequential machines (ISSM). In this chapter we explain the computation for weak partition pairs (WPP).

11.1 Principle

The calculation for WPP is basically the same as that in Chapter 5 except we have to make sure that

\[ \Pi = \{A_1, A_2, \ldots, A_m\} \]
\[ \Gamma = \{B_1, B_2, \ldots, B_n\} \]

\((\Pi, \Gamma)\) is an weak S-S pair iff

\[ \forall s, t \in S \quad \forall x \in I:\]
\[ [s]_{\Pi} = [t]_{\Pi} \land s \delta_x \neq 0 \land t \delta_x \neq 0 \]
\[ \implies [s \delta_x]_{\Gamma} = [t \delta_x]_{\Gamma} \quad (11.1) \]

The difference is only that we have to check if \(s \delta_x\) and \(t \delta_x\) are don't cares before we go further. It is the same for other weak pairs. We omit the discussion here.

11.2 Algorithm

Because the transitive property rules out in partition operations on an ISSM, we can not use the way that calculates basic partition pairs. In DASM, we use a procedure to generate a partition. With this partition we obtain a weak m-partition. Continuing the search for all partitions on the set of first component of the pair, we can get all weak partition pairs.
Algorithm COMPPW(PT);
input: machine table arrays; partition type PT;
output: weak partition pairs;
procedure:
begin var BR: boolean;
   PIW1, PIW2: partition;
   L1, J, M1, E, F, NS1: integer;
   NEXTP(L1, J, M1, E, F, BR, PIW);
   do not BR
       NEXTP(L1, J, M1, E, F, BR, PIW1);
       RmPI-W(PT, PIW1, PIW2, J, NS1);
       if NS1>0 and NS1<Num
           PrintP1(PIW, PIW2);
       fi
   od
end

Within the algorithm, procedure NEXTP offers a partition PIW1; RmPI-W calculate out the weak m-partition PIW2 of PIW1. Num is NumStates or NumOutputs depended on pairtype PT.

11.3 Example

Machine table: a:me654w.dat shown in Fig.11.1;
Procedure:
step 1. Run DASM by typing DASM
        under DOS prompt;
step 2. Select the function of
        ISSM by typing I;
step 3. Specify the data file
        by typing a:me654w.dat;
step 4. Select the function of
        weak pairs by typing P;
step 5. Specify the output file
        by typing a:me654w.wpp.

The result is in file a:me654w.wpp and shown in Fig. 11.2.
Fig. 11.2 Weak pairs of a:me654w.dat
